Preface	17
Who Should Use This Guide18
What You'll Find in This Guide.19
Additional References23
Typographic Conventions24
Part 1: Getting Started.	25
Chapter 1. Switch Administration	27
Administration Interfaces28
Browser-Based Interface28
Establishing a Connection29
Using the Switch Management Ports.29
Using the Switch Data Ports30
Using Telnet31
Using Secure Shell.31
Using SSH with Password Authentication32
Using SSH with Public Key Authentication32
Using a Web Browser33
Using Simple Network Management Protocol.36
BOOTP/DHCP Client IP Address Services37
DHCP Host Name Configuration37
DHCP SYSLOG Server.38
Global BOOTP Relay Agent Configuration38
Domain-Specific BOOTP Relay Agent Configuration.39
DHCP Option 8239
DHCP Snooping39
Switch Login Levels.41
Setup vs. the Command Line43
Idle Disconnect.43
Boot Strict Mode44
Acceptable Cipher Suites.46
Configuring Strict Mode47
SSL/TLS Version Limitation48
Limitations.48
Chapter 2. Initial Setup.	49
Information Needed for Setup50
Default Setup Options.50
Stopping and Restarting Setup Manually51
Setup Part 1: Basic System Configuration52
Setup Part 2: Port Configuration54
Setup Part 3: VLANs56

Setup Part 4: IP Configuration	57
IP Interfaces	57
Loopback Interfaces	58
Default Gateways	59
IP Routing	59
Setup Part 5: Final Steps	61
Optional Setup for Telnet Support	62
Chapter 3. Service Location Protocol	63
Active DA Discovery	63
SLP Configuration	64
Chapter 4. Switch Software Management	65
Loading New Software to Your Switch	66
Loading Software via the ISCLI	66
Loading Software via BBI	67
USB Options	68
USB Boot	68
USB Copy	69
The Boot Management Menu	70
Recovering from a Failed Software Upgrade	71
Recovering a Failed Boot Image	73
Part 2:. Securing the Switch	75
Chapter 5. Securing Administration	77
Secure Shell and Secure Copy	78
Configuring SSH/SCP Features on the Switch	78
Configuring the SCP Administrator Password	79
Using SSH and SCP Client Commands	79
SSH and SCP Encryption of Management Messages	81
Generating RSA Host Key for SSH Access	81
SSH/SCP Integration with Radius Authentication	81
SSH/SCP Integration with TACACS+ Authentication	81
End User Access Control	82
Considerations for Configuring End User Accounts	82
Strong Passwords	82
User Access Control	83
Listing Current Users	84
Logging into an End User Account	84
Chapter 6. Authentication & Authorization Protocols	85
RADIUS Authentication and Authorization	86
How RADIUS Authentication Works	86
Configuring RADIUS on the Switch	86
RADIUS Authentication Features in Lenovo N/OS	87
Switch User Accounts	88
RADIUS Attributes for Lenovo N/OS User Privileges	88

TACACS+ Authentication90
How TACACS+ Authentication Works.90
TACACS+ Authentication Features in Lenovo N/OS90
Command Authorization and Logging.92
Configuring TACACS+ Authentication on the Switch92
LDAP Authentication and Authorization94
Chapter 7. 802.1X Port-Based Network Access Control 97
Extensible Authentication Protocol over LAN98
EAPoL Authentication Process99
EAPoL Message Exchange	100
EAPoL Port States	101
Guest VLAN	101
Supported RADIUS Attributes	102
EAPoL Configuration Guidelines	104
Chapter 8. Access Control Lists105
Summary of Packet Classifiers	106
Summary of ACL Actions	108
Assigning Individual ACLs to a Port	108
ACL Order of Precedence	109
ACL Metering and Re-Marking.	109
ACL Port Mirroring	111
Viewing ACL Statistics	112
ACL Logging	112
Enabling ACL Logging	112
Logged Information	112
Rate Limiting Behavior	113
Log Interval	113
ACL Logging Limitations	113
ACL Configuration Examples	114
VLAN Maps	117
Using Storm Control Filters	119
Part 3:. Switch Basics121
Chapter 9. VLANs123
VLANs Overview.	124
VLANs and Port VLAN ID Numbers	124
VLAN Numbers	124
PVID/Native VLAN Numbers	125
VLAN Tagging/Trunk Mode	126
VLAN Topologies and Design Considerations	130
Multiple VLANs with Tagging/Trunk Mode Adapters	131
VLAN Configuration Example	133

Protocol-Based VLANs	134
Port-Based vs. Protocol-Based VLANs	135
PVLAN Priority Levels	135
PVLAN Tagging/Trunk Mode	135
PVLAN Configuration Guidelines	135
Configuring PVLAN	136
Private VLANs.	137
Private VLAN Ports	137
Configuration Guidelines	138
Configuration Example	138
Chapter 10. Ports and Trunking	141
Configuring QSFP+ Ports	142
Trunking Overview.	144
Static Trunks.	145
Static Trunk Requirements	145
Static Trunk Group Configuration Rules	145
Configuring a Static Port Trunk.	146
Link Aggregation Control Protocol	148
Static LACP Trunks	149
LACP Port Modes.	149
LACP Individual	150
LACP Minimum Links Option	151
Configuring LACP	151
Configurable Trunk Hash Algorithm	152
Chapter 11. Spanning Tree Protocols	153
Spanning Tree Protocol Modes	154
Global STP Control	155
PVRST Mode	155
Port States	156
Bridge Protocol Data Units	156
Bridge Protocol Data Units Overview	156
Determining the Path for Forwarding BPDUs	156
Simple STP Configuration	159
Per-VLAN Spanning Tree Groups.	161
Using Multiple STGs to Eliminate False Loops	161
VLANs and STG Assignment	161
Manually Assigning STGs	162
Guidelines for Creating VLANs	163
Rules for VLAN Tagged/Trunk Mode Ports.	163
Adding and Removing Ports from STGs	164
The Switch-Centric Model	165
Configuring Multiple STGs	166
Rapid Spanning Tree Protocol	168
Port States	168
RSTP Configuration Guidelines.	168
RSTP Configuration Example.	168

Multiple Spanning Tree Protocol	170
MSTP Region	170
Common Internal Spanning Tree	170
MSTP Configuration Guidelines	170
MSTP Configuration Examples	171
Port Type and Link Type	174
Edge/Portfast Port.	174
Link Type	174
Chapter 12. Virtual Link Aggregation Groups	175
VLAG Capacities	178
VLAGs versus Port Trunks.	178
Configuring VLAGs.	180
Basic VLAG Configuration	181
VLAG Configuration - VLANs Mapped to MSTI.	183
Configuring Health Check	184
VLAGs with VRRP	185
Configuring VLAGs in Multiple Layers	191
Traffic Forwarding	193
Health Check.	194
Chapter 13. Quality of Service.	195
QoS Overview	196
Using ACL Filters.	197
Summary of ACL Actions	197
ACL Metering and Re-Marking	198
Using DSCP Values to Provide QoS	199
Differentiated Services Concepts	199
Per Hop Behavior	200
QoS Levels	201
DSCP Re-Marking and Mapping	202
DSCP Re-Marking Configuration Examples	202
Using 802.1p Priority to Provide QoS	205
Queuing and Scheduling	206
Control Plane Protection.	206
WRED with ECN	207
How WRED/ECN work together	207
Configuring WRED/ECN.	208
WRED/ECN Configuration Example.	209
Part 4:. Advanced Switching Features	213
Chapter 14. Virtualization.	215
Chapter 15. Virtual NICs	217
Defining Server Ports	218
Enabling the vNIC Feature.	218
vNIC IDs	218
vNIC IDs on the Switch	218
vNIC Interface Names on the Server	218

vNIC Bandwidth Metering	219
vNIC Groups	220
vNIC Teaming Failover	221
vNIC Configuration Example	223
Basic vNIC Configuration	223
vNICs for iSCSI on Emulex Endeavor 2	225
Chapter 16. VMready	227
VE Capacity	228
Defining Server Ports	228
VM Group Types	228
Local VM Groups	229
Distributed VM Groups	232
VM Profiles	232
Initializing a Distributed VM Group	233
Assigning Members	233
Synchronizing the Configuration	233
Removing Member VEs	234
VMcheck	235
Virtual Distributed Switch	237
Prerequisites	237
Guidelines	237
Migrating to vDS	238
Virtualization Management Servers	239
Assigning a vCenter	239
vCenter Scans	239
Deleting the vCenter	240
Exporting Profiles	241
VMware Operational Commands	241
Pre-Provisioning VEs	242
VLAN Maps	243
VM Policy Bandwidth Control	244
VM Policy Bandwidth Control Commands	244
Bandwidth Policies vs. Bandwidth Shaping	244
VMready Information Displays	246
VMready Configuration Example	250
Chapter 17. FCoE and CEE	253
Fibre Channel over Ethernet	254
The FCoE Topology	254
FCoE Requirements	255
Converged Enhanced Ethernet	256
Turning CEE On or Off	256
Effects on Link Layer Discovery Protocol	256
Effects on 802.1p Quality of Service	257
Effects on Flow Control	258

FCoE Initialization Protocol Snooping	259
Port Trunking	259
Global FIP Snooping Settings	259
FIP Snooping for Specific Ports	260
Port FCF and ENode Detection	260
FCoE Connection Timeout	260
FCoE ACL Rules	261
FCoE VLANs	261
Viewing FIP Snooping Information	262
Operational Commands	262
FIP Snooping Configuration	263
Priority-Based Flow Control	264
Global Configuration	264
PFC Configuration Example	266
Enhanced Transmission Selection	268
802.1p Priority Values	268
Priority Groups	269
PGID	269
Assigning Priority Values to a Priority Group	270
Deleting a Priority Group	270
Allocating Bandwidth	270
Configuring ETS	271
Data Center Bridging Capability Exchange	274
DCBX Settings	274
Configuring DCBX	276
FCoE Example Configuration	278
Chapter 18. Fibre Channel	281
Ethernet vs. Fibre Channel	282
Supported Switch Roles	283
Implementing Fibre Channel	285
Port Modes	285
Fibre Channel VLANs	286
Port Membership	286
Switching Mode	287
NPV Gateway	287
NPV Port Traffic Mapping	287
NPV Manual Disruptive Load-Balancing	288
Full Fabric Zoning	288
Zones	289
Zonesets	290
Defining Zoning	290
Activating a Zoneset	292
E_Ports	292
Optimized FCoE Traffic Flow	294
Storage Management Initiative Specification (SMI-S)	295
Fibre Channel Configuration	296
Configuration Guidelines	296
Example 1: NPV Gateway	296
Example 2: Full Fabric FC/FCoE Switch	297

Fibre Channel Standard Protocols Supported.	299
Chapter 19. Edge Virtual Bridging	301
EVB Operations Overview.	302
VSIDB Synchronization	302
VLAN Behavior	303
Manual Reflective Relay	303
EVB Configuration	304
Limitations	306
Unsupported features.	306
Chapter 20. Static Multicast ARP	307
Configuring Static Multicast ARP.	308
Configuration Example	308
Limitations	309
Part 5:. IP Routing	311
Chapter 21. Basic IP Routing	313
IP Routing Benefits	314
Routing Between IP Subnets	314
Example of Subnet Routing	315
Using VLANs to Segregate Broadcast Domains	316
Configuration Example	316
ECMP Static Routes.	319
OSPF Integration	319
ECMP Route Hashing	319
Configuring ECMP Static Routes	320
Dynamic Host Configuration Protocol.	321
Chapter 22. Internet Protocol Version 6	323
IPv6 Limitations	324
IPv6 Address Format	325
IPv6 Address Types	326
IPv6 Address Autoconfiguration	328
IPv6 Interfaces	329
Neighbor Discovery	330
Supported Applications	332
Configuration Guidelines	333
IPv6 Configuration Examples	334
Chapter 23. IPsec with IPv6	337
IPsec Protocols	338

Using IPsec with the RackSwitch G8264CS	339
Setting up Authentication	339
Creating an IKEv2 Proposal.	340
Importing an IKEv2 Digital Certificate	340
Generating an IKEv2 Digital Certificate.	341
Enabling IKEv2 Preshared Key Authentication	341
Setting Up a Key Policy	342
Using a Manual Key Policy.	343
Using a Dynamic Key Policy	345
Chapter 24. Routing Information Protocol	347
Distance Vector Protocol.	348
Stability	348
Routing Updates	348
RIPv1	349
RIPv2	349
RIPv2 in RIPv1 Compatibility Mode.	349
RIP Features	350
RIP Configuration Example	351
Chapter 25. Internet Group Management Protocol	353
IGMP Terms	354
How IGMP Works	355
IGMP Capacity and Default Values	356
IGMP Snooping	357
IGMP Querier	357
IGMP Groups	358
IGMPv3 Snooping.	358
IGMP Snooping Configuration Guidelines	360
IGMP Snooping Configuration Example	361
Advanced Configuration Example: IGMP Snooping	362
Prerequisites	363
Configuration.	363
Troubleshooting	367
IGMP Relay	370
Configuration Guidelines	370
Configure IGMP Relay.	371
Advanced Configuration Example: IGMP Relay.	372
Prerequisites	372
Configuration.	373
Troubleshooting	376
Additional IGMP Features	379
FastLeave	379
IGMP Filtering	379
Static Multicast Router.	380
Chapter 26. Multicast Listener Discovery	381
MLD Terms	382

How MLD Works	383
MLD Querier.	384
Dynamic M routers	385
MLD Capacity and Default Values	386
Configuring MLD	387
Chapter 27. Border Gateway Protocol	389
Internal Routing Versus External Routing	390
Route Reflector	391
Restrictions.	393
Forming BGP Peer Routers	394
Static Peers.	394
Dynamic Peers	394
Loopback Interfaces	396
What is a Route Map?.	396
Next Hop Peer IP Address	397
Incoming and Outgoing Route Maps	397
Precedence.	398
Configuration Overview	398
Aggregating Routes.	400
Redistributing Routes.	400
BGP Communities	401
BGP Attributes.	402
Selecting Route Paths in BGP.	404
Equal Cost Multi-Path.	404
Multipath Relax	404
BGP Failover Configuration	405
Default Redistribution and Route Aggregation Example.	407
Chapter 28. OSPF.	409
OSPFv2 Overview	410
Types of OSPF Areas	410
Types of OSPF Routing Devices.	411
Neighbors and Adjacencies	412
The Link-State Database	412
The Shortest Path First Tree	414
Internal Versus External Routing	414

OSPFv2 Implementation in Lenovo N/OS	415
Configurable Parameters	415
Defining Areas	416
Assigning the Area Index	416
Using the Area ID to Assign the OSPF Area Number	417
Attaching an Area to a Network	417
Interface Cost	418
Electing the Designated Router and Backup	418
Summarizing Routes	418
Default Routes	419
Virtual Links	420
Router ID	420
Authentication	421
Configuring Plain Text OSPF Passwords	422
Configuring MD5 Authentication	422
Host Routes for Load Balancing	423
Loopback Interfaces in OSPF	424
OSPF Features Not Supported in This Release	424
OSPFv2 Configuration Examples	425
Example 1: Simple OSPF Domain	426
Example 2: Virtual Links	428
Example 3: Summarizing Routes	432
Verifying OSPF Configuration	433
OSPFv3 Implementation in Lenovo N/OS	434
OSPFv3 Differences from OSPFv2	434
OSPFv3 Requires IPv6 Interfaces	434
OSPFv3 Uses Independent Command Paths	434
OSPFv3 Identifies Neighbors by Router ID	435
Other Internal Improvements	435
OSPFv3 Limitations	435
OSPFv3 Configuration Example	435
Neighbor Configuration Example	438
Chapter 29. Protocol Independent Multicast	439
PIM Overview	440
Supported PIM Modes and Features	441
Basic PIM Settings	442
Globally Enabling or Disabling the PIM Feature	442
Defining a PIM Network Component	442
Defining an IP Interface for PIM Use	442
PIM Neighbor Filters	443
Additional Sparse Mode Settings	445
Specifying the Rendezvous Point	445
Influencing the Designated Router Selection	445
Specifying a Bootstrap Router	446
Configuring a Loopback Interface	446
Using PIM with Other Features	448
PIM with ACLs or VMAPs	448
PIM with IGMP	448
PIM Configuration Examples	449

Part 6:. High Availability Fundamentals	453
Chapter 30. Basic Redundancy	455
Trunking for Link Redundancy	456
Virtual Link Aggregation	456
Hot Links	457
Forward Delay	457
Preemption	457
FDB Update	457
Configuration Guidelines	457
Configuring Hot Links	458
Chapter 31. Layer 2 Failover	459
Monitoring Trunk Links	459
Setting the Failover Limit	460
Manually Monitoring Port Links	461
L2 Failover with Other Features	462
Static Trunks	462
LACP	462
Spanning Tree Protocol	462
Configuration Guidelines	463
Configuring Layer 2 Failover	463
Chapter 32. Virtual Router Redundancy Protocol	465
VRRP Overview	466
VRRP Components	466
VRRP Operation	467
Selecting the Master VRRP Router	468
Failover Methods	469
Active-Active Redundancy	469
Virtual Router Group	469
Lenovo N/OS Extensions to VRRP	470
Virtual Router Deployment Considerations	471
High Availability Configurations	472
VRRP High-Availability Using Multiple VIRs	472
VRRP High-Availability Using VLAGs	476
Part 7:. Network Management	477
Chapter 33. Link Layer Discovery Protocol	479
LLDP Overview	480
Enabling or Disabling LLDP	481
Global LLDP Setting	481
Transmit and Receive Control	481

LLDP Transmit Features	482
Scheduled Interval	482
Minimum Interval.	482
Time-to-Live for Transmitted Information	482
Trap Notifications.	483
Changing the LLDP Transmit State	483
Types of Information Transmitted.	484
LLDP Receive Features	486
Types of Information Received	486
Viewing Remote Device Information	486
Time-to-Live for Received Information.	488
LLDP Example Configuration	490
Chapter 34. Simple Network Management Protocol	491
SNMP Version 1 & Version 2	492
SNMP Version 3	493
Configuring SNMP Trap Hosts	498
SNMP MIBs	501
Switch Images and Configuration Files	507
Loading a New Switch Image.	508
Loading a Saved Switch Configuration.	508
Saving the Switch Configuration	509
Saving a Switch Dump.	509
Part 8:. Monitoring	511
Chapter 35. Remote Monitoring	513
RMON Overview.	513
RMON Group 1—Statistics.	514
RMON Group 2—History	515
History MIB Object ID	515
Configuring RMON History	515
RMON Group 3—Alarms	516
Alarm MIB objects	516
Configuring RMON Alarms	516
RMON Group 9—Events	518

Taiwan Class A compliance statement.	542
Index	543

Preface

The *Lenovo RackSwitch G8264CS Application Guide for Lenovo N/OS 8.2* describes how to configure and use the Lenovo Networking OS 8.2 software on the RackSwitch G8264CS (referred to as G8264CS throughout this document). For documentation on installing the switch physically, see the *Installation Guide* for your G8264CS.

Who Should Use This Guide

This guide is intended for network installers and system administrators engaged in configuring and maintaining a network. The administrator should be familiar with Ethernet concepts, IP addressing, Spanning Tree Protocol, and SNMP configuration parameters.

What You'll Find in This Guide

This guide will help you plan, implement, and administer Lenovo N/OS software. Where possible, each section provides feature overviews, usage examples, and configuration instructions. The following material is included:

Part 1: Getting Started

This material is intended to help those new to N/OS products with the basics of switch management. This part includes the following chapters:

- [Chapter 1, “Switch Administration,”](#) describes how to access the G8264CS to configure the switch and view switch information and statistics. This chapter discusses a variety of manual administration interfaces, including local management via the switch console, and remote administration via Telnet, a web browser, or via SNMP.
- [Chapter 2, “Initial Setup,”](#) describes how to use the built-in Setup utility to perform first-time configuration of the switch.
- [Chapter 3, “Service Location Protocol,”](#) describes the Service Location Protocol (SLP) that allows the switch to provide dynamic directory services.
- [Chapter 4, “Switch Software Management,”](#) describes how to update the N/OS software operating on the switch.

Part 2: Securing the Switch

- [Chapter 5, “Securing Administration,”](#) describes methods for using Secure Shell for administration connections, and configuring end-user access control.
- [Chapter 6, “Authentication & Authorization Protocols,”](#) describes different secure administration for remote administrators. This includes using Remote Authentication Dial-in User Service (RADIUS), as well as TACACS+ and LDAP.
- [Chapter 7, “802.1X Port-Based Network Access Control,”](#) describes how to authenticate devices attached to a LAN port that has point-to-point connection characteristics. This feature prevents access to ports that fail authentication and authorization and provides security to ports of the G8264CS that connect to blade servers.
- [Chapter 8, “Access Control Lists,”](#) describes how to use filters to permit or deny specific types of traffic, based on a variety of source, destination, and packet attributes.

Part 3: Switch Basics

- [Chapter 9, “VLANs,”](#) describes how to configure Virtual Local Area Networks (VLANs) for creating separate network segments, including how to use VLAN tagging for devices that use multiple VLANs. This chapter also describes Protocol-based VLANs, and Private VLANs.
- [Chapter 10, “Ports and Trunking,”](#) describes how to group multiple physical ports together to aggregate the bandwidth between large-scale network devices.

- [Chapter 11, “Spanning Tree Protocols,”](#) discusses how Spanning Tree Protocol (STP) configures the network so that the switch selects the most efficient path when multiple paths exist. Covers Rapid Spanning Tree Protocol (RSTP), Per-VLAN Rapid Spanning Tree (PVRST), and Multiple Spanning Tree Protocol (MSTP).
- [Chapter 12, “Virtual Link Aggregation Groups,”](#) describes using Virtual Link Aggregation Groups (VLAG) to form trunks spanning multiple VLAG-capable aggregator switches.
- [Chapter 13, “Quality of Service,”](#) discusses Quality of Service (QoS) features, including IP filtering using Access Control Lists (ACLs), Differentiated Services, and IEEE 802.1p priority values.

Part 4: Advanced Switching Features

- [Chapter 14, “Virtualization,”](#) provides an overview of allocating resources based on the logical needs of the data center, rather than on the strict, physical nature of components.
- [Chapter 15, “Virtual NICs,”](#) discusses using virtual NIC (vNIC) technology to divide NICs into multiple logical, independent instances.
- [Chapter 16, “VMready,”](#) discusses virtual machine (VM) support on the G8264CS.
- [Chapter 17, “FCoE and CEE,”](#) discusses using various Converged Enhanced Ethernet (CEE) features such as Priority-based Flow Control (PFC), Enhanced Transmission Selection (ETS), and FIP Snooping for solutions such as Fibre Channel over Ethernet (FCoE).
- [Chapter 18, “Fibre Channel,”](#) describes how to configure the G8264CS for use with Fibre Channel networks.
- [Chapter 19, “Edge Virtual Bridging \(EVB\)”](#) discusses the IEEE 802.1Qbg—a standards-based protocol that defines how virtual Ethernet bridges exchange configuration information. EVB bridges the gap between physical and virtual network resources, thus simplifying network management.
- [Chapter 20, “Static Multicast ARP”](#) discusses the configuration of a static ARP entry with multicast MAC address for Microsoft’s Network Load Balancing (NLB) feature to function efficiently.

Part 5: IP Routing

- [Chapter 21, “Basic IP Routing,”](#) describes how to configure the G8264CS for IP routing using IP subnets, BOOTP, and DHCP Relay.
- [Chapter 22, “Internet Protocol Version 6,”](#) describes how to configure the G8264CS for IPv6 host management.
- [Chapter 23, “IPsec with IPv6,”](#) describes how to configure Internet Protocol Security (IPsec) for securing IP communications by authenticating and encrypting IP packets, with emphasis on Internet Key Exchange version 2, and authentication/confidentiality for OSPFv3.
- [Chapter 24, “Routing Information Protocol,”](#) describes how the N/OS software implements standard Routing Information Protocol (RIP) for exchanging TCP/IP route information with other routers.

- [Chapter 25, “Internet Group Management Protocol,”](#) describes how the N/OS software implements IGMP Snooping or IGMP Relay to conserve bandwidth in a multicast-switching environment.
- [Chapter 26, “Multicast Listener Discovery,”](#) describes how Multicast Listener Discovery (MLD) is used with IPv6 to support host users requests for multicast data for a multicast group.
- [Chapter 27, “Border Gateway Protocol,”](#) describes Border Gateway Protocol (BGP) concepts and features supported in N/OS.
- [Chapter 28, “OSPF,”](#) describes key Open Shortest Path First (OSPF) concepts and their implemented in N/OS, and provides examples of how to configure your switch for OSPF support.
- [Chapter 29, “Protocol Independent Multicast,”](#) describes how multicast routing can be efficiently accomplished using the Protocol Independent Multicast (PIM) feature.

Part 6: High Availability Fundamentals

- [Chapter 30, “Basic Redundancy,”](#) describes how the G8264CS supports redundancy through trunking and hotlinks.
- [Chapter 31, “Layer 2 Failover,”](#) describes how the G8264CS supports high-availability network topologies using Layer 2 Failover.
- [Chapter 32, “Virtual Router Redundancy Protocol,”](#) describes how the G8264CS supports high-availability network topologies using Virtual Router Redundancy Protocol (VRRP).

Part 7: Network Management

- [Chapter 33, “Link Layer Discovery Protocol,”](#) describes how Link Layer Discovery Protocol helps neighboring network devices learn about each others’ ports and capabilities.
- [Chapter 34, “Simple Network Management Protocol,”](#) describes how to configure the switch for management through an SNMP client.

Part 8: Monitoring

- [Chapter 35, “Remote Monitoring,”](#) describes how to configure the RMON agent on the switch, so that the switch can exchange network monitoring data.
- [Chapter 36, “sFlow,”](#) described how to use the embedded sFlow agent for sampling network traffic and providing continuous monitoring information to a central sFlow analyzer.
- [Chapter 37, “Port Mirroring,”](#) discusses tools how copy selected port traffic to a monitor port for network analysis.

Part 9: Appendices

- [Appendix A, “Glossary,”](#) describes common terms and concepts used throughout this guide.
- [Appendix B, “Getting help and technical assistance,”](#) provides details on where to go for additional information about Lenovo and Lenovo products.

- [Appendix C, “Notices,”](#) contains copyright and trademark notices.

Additional References

Additional information about installing and configuring the G8264CS is available in the following guides:

Typographic Conventions

The following table describes the typographic styles used in this book.

Table 1. *Typographic Conventions*

Typeface or Symbol	Meaning	Example
ABC123	This type is used for names of commands, files, and directories used within the text. It also depicts on-screen computer output and prompts.	View the readme . txt file. Main#
ABC123	This bold type appears in command examples. It shows text that must be typed in exactly as shown.	Main# sys
<ABC123>	This italicized type appears in command examples as a parameter placeholder. Replace the indicated text with the appropriate real name or value when using the command. Do not type the brackets. This also shows book titles, special terms, or words to be emphasized.	To establish a Telnet session, enter: host# telnet <IP address> Read your <i>User's Guide</i> thoroughly.
[]	Command items shown inside brackets are optional and can be used or excluded as the situation demands. Do not type the brackets.	host# ls [-a]
	The vertical bar () is used in command examples to separate choices where multiple options exist. Select only one of the listed options. Do not type the vertical bar.	host# set left right
AaBbCc123	This block type depicts menus, buttons, and other controls that appear in Web browsers and other graphical interfaces.	Click the Save button.

Part 1: Getting Started

Chapter 1. Switch Administration

Your RackSwitch G8264CS (G8264CS) is ready to perform basic switching functions right out of the box. Some of the more advanced features, however, require some administrative configuration before they can be used effectively.

The extensive Lenovo Networking OS switching software included in the G8264CS provides a variety of options for accessing the switch to perform configuration, and to view switch information and statistics.

This chapter discusses the various methods that can be used to administer the switch.

Administration Interfaces

Lenovo N/OS provides a variety of user-interfaces for administration. These interfaces vary in character and in the methods used to access them: some are text-based, and some are graphical; some are available by default, and some require configuration; some can be accessed by local connection to the switch, and others are accessed remotely using various client applications. For example, administration can be performed using any of the following:

- A built-in, text-based command-line interface and menu system for access via serial-port connection or an optional Telnet or SSH session
- The built-in Browser-Based Interface (BBI) available using a standard web-browser
- SNMP support for access through network management software such as IBM Director or HP OpenView

The specific interface chosen for an administrative session depends on user preferences, as well as the switch configuration and the available client tools.

In all cases, administration requires that the switch hardware is properly installed and turned on. (see the *RackSwitch G8264CS Installation Guide*).

Browser-Based Interface

The Browser-based Interface (BBI) provides access to the common configuration, management and operation features of the G8264CS through your Web browser.

For more information, refer to the *BBI Quick Guide*.

Establishing a Connection

The factory default settings permit initial switch administration through *only* the built-in serial port. All other forms of access require additional switch configuration before they can be used.

Remote access using the network requires the accessing terminal to have a valid, routable connection to the switch interface. The client IP address may be configured manually, or an IPv4 address can be provided automatically through the switch using a service such as DHCP or BOOTP relay (see [“BOOTP/DHCP Client IP Address Services” on page 37](#)), or an IPv6 address can be obtained using IPv6 stateless address configuration.

Note: Throughout this manual, *IP address* is used in places where either an IPv4 or IPv6 address is allowed. IPv4 addresses are entered in dotted-decimal notation (for example, 10.10.10.1), while IPv6 addresses are entered in hexadecimal notation (for example, 2001:db8:85a3::8a2e:370:7334). In places where only one type of address is allowed, *IPv4 address* or *IPv6 address* is specified.

Using the Switch Management Ports

To manage the switch through the management ports, you must configure an IP interface for each management interface. Configure the following IPv4 parameters:

- IP address/mask
- Default gateway address

1. Log on to the switch.
2. Enter Global Configuration mode.

```
RS 8264CS> enable
RS 8264CS# configure terminal
```

3. Configure a management IP address and mask:

```
RS 8264CS(config)# interface ip 128
RS 8264CS(config-ip-if)# ip address <management interface IPv4 address>
RS 8264CS(config-ip-if)# ip netmask <IPv4 subnet mask>
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

4. Configure the appropriate default gateway.

IP gateway 4 is required for IF 128.

```
RS 8264CS(config)# ip gateway 4 address <default gateway IPv4 address>
RS 8264CS(config)# ip gateway 4 enable
```

Once you configure a management IP address for your switch, you can connect to a management port and use the Telnet program from an external management station to access and control the switch. The management port provides *out-of-band* management.

Using the Switch Data Ports

You also can configure *in-band* management through any of the switch data ports. To allow in-band management, use the following procedure:

1. Log on to the switch.
2. Enter IP interface mode.

```
RS 8264CS> enable
RS 8264CS# configure terminal
RS 8264CS(config)# interface ip <IP interface number>
```

Note: Interface 128 is reserved for out-of-band management (see [“Using the Switch Management Ports” on page 29](#)).

3. Configure the management IP interface/mask.
 - o Using IPv4:

```
RS 8264CS(config-ip-if)# ip address <management interface IPv4 address>
RS 8264CS(config-ip-if)# ip netmask <IPv4 subnet mask>
```

- o Using IPv6:

```
RS 8264CS(config-ip-if)# ipv6 address <management interface IPv6 address>
RS 8264CS(config-ip-if)# ipv6 prefixlen <IPv6 prefix length>
```

4. Configure the VLAN, and enable the interface.

```
RS 8264CS(config-ip-if)# vlan 1
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

5. Configure the default gateway.

- o If using IPv4:

```
RS 8264CS(config)# ip gateway <gateway number> address <IPv4 address>
RS 8264CS(config)# ip gateway <gateway number> enable
```

- o If using IPv6:

```
RS 8264CS(config)# ip gateway6 <gateway number> address <IPv6 address>
RS 8264CS(config)# ip gateway6 <gateway number> enable
```

Note: Gateway 1, 2, and 3 are used for in-band data networks. Gateway 4 is reserved for the out-of-band management port (see [“Using the Switch Management Ports” on page 29](#)).

Once you configure the IP address and have a network connection, you can use the Telnet program from an external management station to access and control the switch. Once the default gateway is enabled, the management station and your switch do not need to be on the same IP subnet.

The G8264CS supports an industry standard command-line interface (ISCLI) that you can use to configure and control the switch over the network using the Telnet program. You can use the ISCLI to perform many basic network management functions. In addition, you can configure the switch for management using an SNMP-based network management system or a Web browser.

For more information, see the documents listed in [“Additional References” on page 23](#).

Using Telnet

A Telnet connection offers the convenience of accessing the switch from a workstation connected to the network. Telnet access provides the same options for user and administrator access as those available through the console port.

By default, Telnet access is enabled. Use the following commands to disable or re-enable Telnet access:

```
RS 8264CS(config)# [no] access telnet enable
```

Once the switch is configured with an IP address and gateway, you can use Telnet to access switch administration from any workstation connected to the management network.

To establish a Telnet connection with the switch, run the Telnet program on your workstation and issue the following Telnet command:

```
telnet <switch IPv4 or IPv6 address>
```

You will then be prompted to enter a password as explained [“Switch Login Levels” on page 41](#).

Two attempts are allowed to log in to the switch. After the second unsuccessful attempt, the Telnet client is disconnected via TCP session closure.

Using Secure Shell

Although a remote network administrator can manage the configuration of a G8264CS via Telnet, this method does not provide a secure connection. The Secure Shell (SSH) protocol enables you to securely log into another device over a network to execute commands remotely. As a secure alternative to using Telnet to manage switch configuration, SSH ensures that all data sent over the network is encrypted and secure.

The switch can do only one session of key/cipher generation at a time. Thus, a SSH/SCP client will not be able to login if the switch is doing key generation at that time. Similarly, the system will fail to do the key generation if a SSH/SCP client is logging in at that time.

The supported SSH encryption and authentication methods are:

- Server Host Authentication: Client RSA-authenticates the switch when starting each connection

- Key Exchange: ecdh-sha2-nistp521, ecdh-sha2-nistp384, ecdh-sha2-nistp256, ecdh-sha2-nistp224, ecdh-sha2-nistp192, rsa2048-sha256, rsa1024-sha1, diffie-hellman-group-exchange-sha256, diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, diffie-hellman-group1-sha1
- Encryption: aes128-ctr, aes128-cbc, rijndael128-cbc, blowfish-cbc,3des-cbc, arcfour256, arcfour128, arcfour
- MAC: hmac-sha1, hmac-sha1-96, hmac-md5, hmac-md5-96
- User Authentication: Local password authentication, public key authentication, RADIUS, TACACS+

Lenovo Networking OS implements the SSH version 2.0 standard and is confirmed to work with SSH version 2.0-compliant clients such as the following:

- OpenSSH_5.4p1 for Linux
- Secure CRT Version 5.0.2 (build 1021)
- Putty SSH release 0.60

Using SSH with Password Authentication

By default, the SSH feature is disabled. Once the IP parameters are configured and the SSH service is enabled, you can access the command line interface using an SSH connection.

To establish an SSH connection with the switch, run the SSH program on your workstation by issuing the SSH command, followed by the switch IPv4 or IPv6 address:

```
# ssh <switch IP address>
```

You will then be prompted to enter a password as explained [“Switch Login Levels” on page 41](#).

Using SSH with Public Key Authentication

SSH can also be used for switch authentication based on asymmetric cryptography. Public encryption keys can be uploaded on the switch and used to authenticate incoming login attempts based on the clients’ private encryption key pairs. After a predefined number of failed public key login attempts, the switch reverts to password-based authentication.

To set up public key authentication:

1. Enable SSH:

```
RS 8264CS(config)# ssh enable
```

2. Import the public key file using SFTP or TFTP for the admin user account::

```
RS 8264CS(config)# copy {sftp|tftp} public-key
Port type ["DATA"/"MGT"]: mgt
Address or name of remote host: 9.43.101.151
Source file name: 11.key
Username of the public key: admin
Confirm download operation (y/n) ? y
```

Notes:

- When prompted to input a username, a valid user account name must be entered. If no username is entered, the key is stored on the switch, and can be assigned to a user account later.
 - A user account can have up to 100 public keys set up on the switch.
 - The switch supports ssh public keys for up to 20 local switch users or administrators.
 - The maximum number of failed public key authentication attempts is 20; the default is 3.
3. Configure a maximum number of 3 failed public key authentication attempts before the system reverts to password-based authentication:

```
RS 8264CS(config)# ssh maxauthattempts 3
```

Once the public key is configured on the switch, the client can use SSH to login from a system where the private key pair is set up:

```
# ssh <switch IP address>
```

Using a Web Browser

The switch provides a Browser-Based Interface (BBI) for accessing the common configuration, management and operation features of the G8264CS through your Web browser.

By default, BBI access via HTTP is enabled on the switch.

You can also access the BBI directly from an open Web browser window. Enter the URL using the IP address of the switch interface (for example, `http://<IPv4 or IPv6 address>`).

Configuring HTTP Access to the BBI

By default, BBI access via HTTP is enabled on the switch.

To disable or re-enable HTTP access to the switch BBI, use the following commands:

```
RS 8264CS(config)# access http enable (Enable HTTP access)  
-or-  
RS 8264CS(config)# no access http enable (Disable HTTP access)
```

The default HTTP web server port to access the BBI is port 80. However, you can change the default Web server port with the following command:

```
RS 8264CS(config)# access http port <TCP port number>
```

To access the BBI from a workstation, open a Web browser window and type in the URL using the IP address of the switch interface (for example, `http://<IPv4 or IPv6 address>`).

Configuring HTTPS Access to the BBI

The BBI can also be accessed via a secure HTTPS connection over management and data ports.

1. Enable HTTPS.

By default, BBI access via HTTPS is disabled on the switch. To enable BBI Access via HTTPS, use the following command:

```
RS 8264CS(config)# access https enable
```

2. Set the HTTPS server port number (optional).

To change the HTTPS Web server port number from the default port 443, use the following command:

```
RS 8264CS(config)# access https port <x>
```

3. Generate the HTTPS certificate.

Accessing the BBI via HTTPS requires that you generate a certificate to be used during the key exchange. A default certificate is created the first time HTTPS is enabled, but you can create a new certificate defining the information you want to be used in the various fields.

```
RS 8264CS(config)# access https generate-certificate
Country Name (2 letter code) []: <country code>
State or Province Name (full name) []: <state>
Locality Name (eg, city) []: <city>
Organization Name (eg, company) []: <company>
Organizational Unit Name (eg, section) []: <org. unit>
Common Name (eg, YOUR name) []: <name>
Email (eg, email address) []: <email address>
Confirm generating certificate? [y/n]: y
Generating certificate. Please wait (approx 30 seconds)
restarting SSL agent
```

4. Save the HTTPS certificate.

The certificate is valid only until the switch is rebooted. To save the certificate so it is retained beyond reboot or power cycles, use the following command:

```
RS 8264CS(config)# access https save-certificate
```

When a client (such as a web browser) connects to the switch, the client is asked to accept the certificate and verify that the fields match what is expected. Once BBI access is granted to the client, the BBI can be used as described in the *Lenovo Networking OS 8.2 BBI Quick Guide*.

Browser-Based Interface Summary

The BBI is organized at a high level as follows:

Context buttons—These buttons allow you to select the type of action you wish to perform. The *Configuration* button provides access to the configuration elements for the entire switch. The *Statistics* button provides access to the switch statistics and state information. The *Dashboard* button allows you to display the settings and operating status of a variety of switch features.

Navigation Window—This window provides a menu list of switch features and functions:

- **System**—this folder provides access to the configuration elements for the entire switch.
- **Switch Ports**—Configure each of the physical ports on the switch.
- **Port-Based Port Mirroring**—Configure port mirroring behavior.
- **Layer 2**—Configure Layer 2 features for the switch.
- **RMON Menu**—Configure Remote Monitoring features for the switch.
- **Layer 3**—Configure Layer 3 features for the switch.
- **QoS**—Configure Quality of Service features for the switch.
- **Access Control**—Configure Access Control Lists to filter IP packets.
- **CEE**—Configure Converged Enhanced Ethernet (CEE).
- **FCoE**—Configure FibreChannel over Ethernet (FCoE).
- **Virtualization**—Configure vNICs and VMready for virtual machine (VM) support.

Using Simple Network Management Protocol

N/OS provides Simple Network Management Protocol (SNMP) version 1, version 2, and version 3 support for access through any network management software, such as IBM Director or HP-OpenView.

Note: SNMP read and write functions are enabled by default. For best security practices, if SNMP is not needed for your network, it is recommended that you disable these functions prior to connecting the switch to the network.

To access the SNMP agent on the G8264CS, the read and write community strings on the SNMP manager must be configured to match those on the switch. The default read community string on the switch is `public` and the default write community string is `private`.

The read and write community strings on the switch can be configured using the following commands:

```
RS 8264CS(config)# snmp-server read-community <1-32 characters>
-and-
RS 8264CS(config)# snmp-server write-community <1-32 characters>
```

The SNMP manager must be able to reach any one of the IP interfaces on the switch.

For the SNMP manager to receive the SNMPv1 traps sent out by the SNMP agent on the switch, configure the trap host on the switch with the following commands:

```
RS 8264CS(config)# snmp-server trap-source <trap source IP interface>
RS 8264CS(config)# snmp-server host <IPv4 address> <trap host community string>
```

To restrict SNMP access to specific IPv4 subnets, use the following commands:

```
RS 8264CS(config)# access management-network <IPv4 address> <subnet mask> snmp-ro
-and-
RS 8264CS(config)# access management-network <IPv4 address> <subnet mask> snmp-rw
```

For IPv6 networks, use:

```
RS 8264CS(config)# access management-network6 <IPv6 address> <IPv6 prefix length>
snmp-ro
-and-
RS 8264CS(config)# access management-network6 <IPv6 address> <IPv6 prefix length>
snmp-rw
```

Note: Subnets allowed for SNMP read-only access must not overlap with subnets allowed for SNMP read-write access.

For more information on SNMP usage and configuration, see [“Simple Network Management Protocol” on page 491](#).

BOOTP/DHCP Client IP Address Services

For remote switch administration, the client terminal device must have a valid IP address on the same network as a switch interface. The IP address on the client device may be configured manually, or obtained automatically using IPv6 stateless address configuration, or an IPv4 address may be obtained automatically via BOOTP or DHCP relay as discussed in the next section.

The G8264CS can function as a relay agent for Bootstrap Protocol (BOOTP) or DHCP. This allows clients to be assigned an IPv4 address for a finite lease period, reassigning freed addresses later to other clients.

Acting as a relay agent, the switch can forward a client's IPv4 address request to up to five BOOTP/DHCP servers. In addition to the five global BOOTP/DHCP servers, up to five domain-specific BOOTP/DHCP servers can be configured for each of up to 10 VLANs.

When a switch receives a BOOTP/DHCP request from a client seeking an IPv4 address, the switch acts as a proxy for the client. The request is forwarded as a UDP Unicast MAC layer message to the BOOTP/DHCP servers configured for the client's VLAN, or to the global BOOTP/DHCP servers if no domain-specific BOOTP/DHCP servers are configured for the client's VLAN. The servers respond to the switch with a Unicast reply that contains the IPv4 default gateway and the IPv4 address for the client. The switch then forwards this reply back to the client.

DHCP is described in RFC 2131, and the DHCP relay agent supported on the G8264CS is described in RFC 1542. DHCP uses UDP as its transport protocol. The client sends messages to the server on port 67 and the server sends messages to the client on port 68.

BOOTP and DHCP relay are collectively configured using the BOOTP commands and menus on the G8264CS.

DHCP Host Name Configuration

The G8264CS supports DHCP host name configuration as described in RFC 2132, option 12. DHCP host name configuration is enabled by default.

Host name can be manually configured using the following command:

```
RS 8264CS(confi g)# hostname <name>
```

If the host name is manually configured, the switch does not replace it with the host name received from the DHCP server.

After the host name is configured on the switch, if DHCP or DHCP host name configuration is disabled, the switch retains the host name.

The switch prompt displays the host name.

Host name configuration can be enabled/disabled using the following command:

```
RS 8264CS(confi g)# [no] system dhcp hostname
```

DHCP SYSLOG Server

During switch startup, if the switch fails to get the configuration file, a message can be recorded in the SYSLOG server.

The G8264CS supports requesting of a SYSLOG server IP address from the DHCP server as described in RFC 2132, option 7. DHCP SYSLOG server request option is enabled by default.

Manually configured SYSLOG server takes priority over DHCP SYSLOG server.

Up to two SYSLOG server addresses received from the DHCP server can be used. The SYSLOG server can be learnt over a management port or a data port.

Use the `RS 8264CS# show logging` command to view the SYSLOG server address.

DHCP SYSLOG server address option can be enabled/disabled using the following command:

```
RS 8264CS(config)# [no] system dhcp syslog
```

Global BOOTP Relay Agent Configuration

To enable the G8264CS to be a BOOTP (or DHCP) forwarder, enable the BOOTP relay feature, configure up to five global BOOTP server IPv4 addresses on the switch, and enable BOOTP relay on the interface(s) on which the client requests are expected.

Generally, it is best to configure BOOTP for the switch IP interface that is closest to the client, so that the BOOTP server knows from which IPv4 subnet the newly allocated IPv4 address will come.

In the G8264CS implementation, there are no primary or secondary BOOTP servers. The client request is forwarded to all the global BOOTP servers configured on the switch (if no domain-specific servers are configured). The use of multiple servers provides failover redundancy. However, no health checking is supported.

1. Use the following commands to configure global BOOTP relay servers:

```
RS 8264CS(config)# ip bootp-relay enable
RS 8264CS(config)# ip bootp-relay server <1-5> address <IPv4 address>
```

2. Enable BOOTP relay on the appropriate IP interfaces.

BOOTP/DHCP Relay functionality may be assigned on a per-interface basis using the following commands:

```
RS 8264CS(config)# interface ip <interface number>
RS 8264CS(config-ip-if)# relay
RS 8264CS(config-ip-if)# exit
```

Domain-Specific BOOTP Relay Agent Configuration

Use the following commands to configure up to five domain-specific BOOTP relay agents for each of up to 10 VLANs:

```
RS 8264CS(config)# ip bootp-relay bcast-domain <1-10> vlan <VLAN number>
RS 8264CS(config)# ip bootp-relay bcast-domain <1-10> server <1-5> address
<IPv4 address>
RS 8264CS(config)# ip bootp-relay bcast-domain <1-10> enable
```

As with global relay agent servers, domain-specific BOOTP/DHCP functionality may be assigned on a per-interface basis (see [Step 2](#) in [page 38](#)).

DHCP Option 82

DHCP Option 82 provides a mechanism for generating IP addresses based on the client device's location in the network. When you enable the DHCP relay agent option on the switch, it inserts the relay agent information option 82 in the packet, and sends a unicast BOOTP request packet to the DHCP server. The DHCP server uses the option 82 field to assign an IP address, and sends the packet, with the original option 82 field included, back to the relay agent. DHCP relay agent strips off the option 82 field in the packet and sends the packet to the DHCP client.

Configuration of this feature is optional. The feature helps resolve several issues where untrusted hosts access the network. See RFC 3046 for details.

Use the following commands to configure DHCP Option 82:

```
RS 8264CS(config)# ip bootp-relay information enable           (Enable Option 82)
RS 8264CS(config)# ip bootp-relay enable                     (Enable DHCP
relay)
RS 8264CS(config)# ip bootp-relay server <1-5> address <IP address>
```

DHCP Snooping

DHCP snooping provides security by filtering untrusted DHCP packets and by building and maintaining a DHCP snooping binding table. This feature is applicable only to IPv4.

An untrusted interface is a port that is configured to receive packets from outside the network or firewall. A trusted interface receives packets only from within the network. By default, all DHCP ports are untrusted.

The DHCP snooping binding table contains the MAC address, IP address, lease time, binding type, VLAN number, and port number that correspond to the local untrusted interface on the switch; it does not contain information regarding hosts interconnected with a trusted interface.

By default, DHCP snooping is disabled on all VLANs. You can enable DHCP snooping on one or more VLANs. You must enable DHCP snooping globally. To enable this feature, enter the following commands:

```
RS 8264CS(config)# ip dhcp snooping vlan <vlan number(s)>
RS 8264CS(config)# ip dhcp snooping
```

Following is an example of DHCP snooping configuration, where the DHCP server and client are in VLAN 100, and the server connects using port 24.

```
RS 8264CS(config)# ip dhcp snooping vlan 100
RS 8264CS(config)# ip dhcp snooping
RS 8264CS(config)# interface port 24
RS 8264CS(config-if)# ip dhcp snooping trust           (Optional; Set port as trusted)
RS 8264CS(config-if)# ip dhcp snooping information option-insert
                                                         (Optional; add DHCP option 82)
RS 8264CS(config-if)# ip dhcp snooping limit rate 100
                                                         (Optional; Set DHCP packet rate)
```

Switch Login Levels

To enable better switch management and user accountability, three levels or *classes* of user access have been implemented on the G8264CS. Levels of access to CLI, Web management functions, and screens increase as needed to perform various switch management tasks. Conceptually, access classes are defined as follows:

- User interaction with the switch is completely passive—nothing can be changed on the G8264CS. Users may display information that has no security or privacy implications, such as switch statistics and current operational state information.
- Operators can only effect temporary changes on the G8264CS. These changes will be lost when the switch is rebooted/reset. Operators have access to the switch management features used for daily switch operations. Because any changes an operator makes are undone by a reset of the switch, operators cannot severely impact switch operation.
- Administrators are the only ones that may make permanent changes to the switch configuration—changes that are persistent across a reboot/reset of the switch. Administrators can access switch functions to configure and troubleshoot problems on the G8264CS. Because administrators can also make temporary (operator-level) changes as well, they must be aware of the interactions between temporary and permanent changes.

Access to switch functions is controlled through the use of unique user names and passwords. Once you are connected to the switch via console, remote Telnet, or SSH, you are prompted to enter a password. The default user names/password for each access level are listed in the following table.

Note: It is recommended that you change default switch passwords after initial configuration and as regularly as required under your network security policies.

Table 2. *User Access Levels - Default Settings*

User Account	Password	Description and Tasks Performed	Status
user	<i>null</i>	The User has no direct responsibility for switch management. He or she can view all switch status information and statistics, but cannot make any configuration changes to the switch.	Disabled
oper	<i>null</i>	The Operator manages all functions of the switch. The Operator can reset ports, except the management ports.	Disabled
admin	admin	The superuser Administrator has complete access to all menus, information, and configuration commands on the G8264CS, including the ability to change both the user and administrator passwords.	Enabled

Note: Access to each user level (except admin account) can be disabled by setting the password to an empty value. To disable admin account, use the command: `RS 8264CS(config)# no access user administrator-enable`. Admin account can be disabled only if there is at least one user account enabled and configured with administrator privilege.

Setup vs. the Command Line

Once the administrator password is verified, you are given complete access to the switch. If the switch is still set to its factory default configuration, the system will ask whether you wish to run Setup (see [“Initial Setup” on page 49](#)), a utility designed to help you through the first-time configuration process. If the switch has already been configured, the command line is displayed instead.

Idle Disconnect

By default, the switch will disconnect your Telnet session after 10 minutes of inactivity. This function is controlled by the idle timeout parameter, which can be set from 0 to 60 minutes, where 0 means the session will never timeout.

Use the following command to set the idle timeout value:

```
RS 8264CS(config)# system idle <0-60>
```

Boot Strict Mode

The implementations specified in this section are compliant with National Institute of Standards and Technology (NIST) Special Publication (SP) 800-131A.

The RackSwitch G8264CS can operate in two boot modes:

- Compatibility mode (default): This is the default switch boot mode. This mode may use algorithms and key lengths that may not be allowed/acceptable by NIST SP 800-131A specification. This mode is useful in maintaining compatibility with previous releases and in environments that have lesser data security requirements.
- Strict mode: Encryption algorithms, protocols, and key lengths in strict mode are compliant with NIST SP 800-131A specification.

When in boot strict mode, the switch uses Secure Sockets Layer (SSL)/Transport Layer Security (TLS) 1.2 protocols to ensure confidentiality of the data to and from the switch.

Before enabling strict mode, ensure the following:

- The software version on all connected switches is Lenovo N/OS 8.2.
- The supported protocol versions and cryptographic cipher suites between clients and servers are compatible. For example: if using SSH to connect to the switch, ensure that the SSH client supports SSHv2 and a strong cipher suite that is compliant with the NIST standard.
- Compliant Web server certificate is installed on the switch, if using BBI.
- A new self-signed certificate is generated for the switch (RS 8264CS(config)# access https generate-certificate). The new certificate is generated using 2048-bit RSA key and SHA-256 digest.
- Protocols that are not NIST SP 800-131A compliant must be disabled or not used.
- Only SSHv2 or higher is used.
- The current configuration, if any, must be saved in a location external to the switch. When the switch reboots, both the startup and running configuration are lost.
- Only protocols/algorithms compliant with NIST SP 800-131A specification are used/enabled on the switch. Please see the NIST SP 800-131A publication for details. The following table lists the acceptable protocols and algorithms:

Table 3. *Acceptable Protocols and Algorithms*

Protocol/Function	Strict Mode Algorithm	Compatibility Mode Algorithm
BGP	BGP does not comply with NIST SP 800-131A specification. When in strict mode, BGP is disabled. However, it can be enabled, if required.	Acceptable
Certificate Generation	RSA-2048 SHA-256	RSA 2048 SHA 256
Certificate Acceptance	RSA 2048 or higher SHA 224 or higher	RSA SHA, SHA2

Table 3. Acceptable Protocols and Algorithms

Protocol/Function	Strict Mode Algorithm	Compatibility Mode Algorithm
HTTPS	TLS 1.2 only See "Acceptable Cipher Suites" on page 46;	TLS 1.0, 1.1, 1.2 See "Acceptable Cipher Suites" on page 46;
IKE		
Key Exchange	DH Group 24	DH group 1, 2, 5, 14, 24
Encryption	3DES, AES-128-CBC	3DES, AES-128-CBC
Integrity	HMAC-SHA1	HMAC-SHA1, HMAC-MD5
IPSec		
AH	HMAC-SHA1	HMAC-SHA1, HMAC-MD5
ESP	3DES, AES-128-CBC, HMAC-SHA1	3DES, AES-128-CBC, HMAC-SHA1, HMAC-MD5
LDAP	LDAP does not comply with NIST SP 800-131A specification. When in strict mode, LDAP is disabled. However, it can be enabled, if required.	Acceptable
OSPF	OSPF does not comply with NIST SP 800-131A specification. When in strict mode, OSPF is disabled. However, it can be enabled, if required.	Acceptable
RADIUS	RADIUS does not comply with NIST SP 800-131A specification. When in strict mode, RADIUS is disabled. However, it can be enabled, if required.	Acceptable
Random Number Generator	NIST SP 800-90A AES CTR DRBG	NIST SP 800-90A AES CTR DRBG
Secure NTP	Secure NTP does not comply with NIST SP 800-131A specification. When in strict mode, secure NTP is disabled. However, it can be enabled, if required.	Acceptable
SLP	SHA-256 or higher RSA/DSA 2048 or higher	
SNMP	SNMPv3 only AES-128-CFB-128/SHA1 Note: Following algorithms are acceptable if you choose to support old SNMPv3 factory default users: AES-128-CFB/SHA1 DES/MD5 AES-128-CFB-128/SHA1	SNMPv1, SNMPv2, SNMPv3 DES/MD5, AES-128-CFB-128/SHA1

Table 3. Acceptable Protocols and Algorithms

Protocol/Function	Strict Mode Algorithm	Compatibility Mode Algorithm
SSH/SFTP		
Host Key	SSH-RSA	SSH-RSA
Key Exchange	ECDH-SHA2-NISTP521 ECDH-SHA2-NISTP384 ECDH-SHA2-NISTP256 ECDH-SHA2-NISTP224 RSA2048-SHA256 DIFFIE-HELL- MAN-GROUP-EXCHANGE-SHA2 56 DIFFIE-HELL- MAN-GROUP-EXCHANGE-SHA1	ECDH-SHA2-NISTP521 ECDH-SHA2-NISTP384 ECDH-SHA2-NISTP256 ECDH-SHA2-NISTP224 ECDH-SHA2-NISTP192 RSA2048-SHA256 RSA1024-SHA1 DIFFIE-HELL- MAN-GROUP-EXCHANGE-SH A256 DIFFIE-HELL- MAN-GROUP-EXCHANGE-SH A1 DIFFIE-HELL- MAN-GROUP14-SHA1 DIFFIE-HELL- MAN-GROUP1-SHA1
Encryption	AES128-CTR AES128-CBC 3DES-CBC	AES128-CTR AES128-CBC RIJNDAEL128-CBC BLOWFISH-CBC 3DES-CBC
MAC	HMAC-SHA1 HMAC-SHA1-96	HMAC-SHA1 HMAC-SHA1-96 HMAC-MD5 HMAC-MD5-96
TACACS+	TACACS+ does not comply with NIST SP 800-131A specification. When in strict mode, TACACS+ is disabled. However, it can be enabled, if required.	Acceptable

Acceptable Cipher Suites

The following cipher suites are acceptable (listed in the order of preference) when the RackSwitch G8264CS is in compatibility mode:

Table 4. List of Acceptable Cipher Suites in Compatibility Mode

Cipher ID	Key Exchange	Authentication	Encryption	MAC	Cipher Name
0xC027	ECDHE	RSA	AES_128_CBC	SHA256	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
0xC013	ECDHE	RSA	AES_128_CBC	SHA1	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
0xC012	ECDHE	RSA	3DES	SHA1	SSL_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
0xC011	ECDHE	RSA		SHA1	SSL_ECDHE_RSA_WITH_RC4_128_SHA
0x002F	RSA	RSA	AES_128_CBC	SHA1	TLS_RSA_WITH_AES_128_CBC_SHA
0x003C	RSA	RSA	AES_128_CBC	SHA256	TLS_RSA_WITH_AES_128_CBC_SHA256
0x0005	RSA	RSA		SHA1	SSL_RSA_WITH_RC4_128_SHA

Table 4. List of Acceptable Cipher Suites in Compatibility Mode (continued)

Cipher ID	Key Exchange	Authentication	Encryption	MAC	Cipher Name
0x000A	RSA	RSA	3DES	SHA1	SSL_RSA_WITH_3DES_EDE_CBC_SHA
0x0033	DHE	RSA	AES-128_CBC	SHA1	TLS_DHE_RSA_WITH_AES_128_CBC_SHA
0x0067	DHE	RSA	AES_128_CBC	SHA256	TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
0x0016	DHE	RSA	3DES	SHA1	SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA

The following cipher suites are acceptable (listed in the order of preference) when the RackSwitch G8264CS is in strict mode:

Table 5. List of Acceptable Cipher Suites in Strict Mode

Cipher ID	Key Exchange	Authentication	Encryption	MAC	Cipher Name
0xC027	ECDSA	RSA	AES_128_CBC	SHA256	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
0xC013	ECDSA	RSA	AES_128_CBC	SHA1	TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
0xC012	ECDSA	RSA	3DES	SHA1	SSL_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
0x0033	DHE	RSA	AES-128_CBC	SHA1	TLS_DHE_RSA_WITH_AES_128_CBC_SHA
0x0067	DHE	RSA	AES_128_CBC	SHA256	TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
0x0016	DHE	RSA	3DES	SHA1	SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
0x002F	RSA	RSA	AES_128_CBC	SHA1	TLS_RSA_WITH_AES_128_CBC_SHA
0x003C	RSA	RSA	AES_128_CBC	SHA256	TLS_RSA_WITH_AES_128_CBC_SHA256
0x000A	RSA	RSA	3DES	SHA1	SSL_RSA_WITH_3DES_EDE_CBC_SHA

Configuring Strict Mode

To change the switch mode to boot strict mode, use the following command:

```
RS 8264CS(config)# [no] boot strict enable
```

When strict mode is enabled, you will see the following message:

```
Warning, security strict mode limits the cryptographic algorithms used by secure protocols on this switch. Please see the documentation for full details, and verify that peer devices support acceptable algorithms before enabling this mode. The mode change will take effect after reloading the switch and the configuration will be wiped during the reload. System will enter security strict mode with default factory configuration at next boot up.
```

```
Do you want SNMPv3 support old default users in strict mode (y/n)?
```

For SNMPv3 default users, see [“SNMP Version 3” on page 493](#).

When strict mode is disabled, the following message is displayed:

```
Warning, disabling security strict mode. The mode change will take effect after reloading the switch.
```

You must reboot the switch for the boot strict mode enable/disable to take effect.

SSL/TLS Version Limitation

Each of the following successive encryption protocol versions provide more security and less compatibility: SSLv3, TLS1.0, TLS1.1, TLS1.2. When negotiating the encryption protocol during the SSL handshake, the switch will accept, by default, the latest (and most secure) protocol version supported by the client equipment. To enforce a minimal level of security acceptable for the connections, use the following command:

```
RS 8264CS(config)# ssl minimum-version {tls10|tls11|tls12}
```

Limitations

In Lenovo N/OS 8.2, consider the following limitation/restrictions if you need to operate the switch in boot strict mode:

- Power ITEs and High-Availability features do not comply with NIST SP 800-131A specification.
- The G8264CS will not discover Platform agents/Common agents that are not in strict mode.
- Web browsers that do not use TLS 1.2 cannot be used.
- Limited functions of the switch managing Windows will be available.

Chapter 2. Initial Setup

To help with the initial process of configuring your switch, the Lenovo Networking OS software includes a Setup utility. The Setup utility prompts you step-by-step to enter all the necessary information for basic configuration of the switch.

Setup can be activated manually from the command line interface any time after login.

Information Needed for Setup

Setup requests the following information:

- Basic system information
 - Date & time
 - Whether to use Spanning Tree Group or not
- Optional configuration for each port
 - Speed, duplex, flow control, and negotiation mode (as appropriate)
 - Whether to use VLAN trunk mode/tagging or not (as appropriate)
- Optional configuration for each VLAN
 - Name of VLAN
 - Which ports are included in the VLAN
- Optional configuration of IP parameters
 - IP address/mask and VLAN for each IP interface
 - IP addresses for default gateway
 - Whether IP forwarding is enabled or not

Default Setup Options

Follow these directions to start system Setup.

1. Connect to the switch.

After connecting, the login prompt appears.

Enter Password:

2. Enter **admin** as the default administrator password.

Note: If the default **admin** login is unsuccessful, or if the administrator Main Menu appears instead, the system configuration has probably been changed from the factory default settings. If desired, return the switch to its factory default configuration.

3. Enter **setup** to start the Setup facility.

Stopping and Restarting Setup Manually

Stopping Setup

To abort the Setup utility, press <Ctrl-C> during any Setup question. When you abort Setup, the system will prompt:

```
Would you like to run from top again? [y/n]
```

Enter **n** to abort Setup, or **y** to restart the Setup program at the beginning.

Restarting Setup

You can restart the Setup utility manually at any time by entering the following command at the configuration prompt:

```
RS 8264CS(config)# setup
```

Setup Part 1: Basic System Configuration

When Setup is started, the system prompts:

"Set Up" will walk you through the configuration of System Date and Time, Spanning Tree, Port Speed/Mode, VLANs, and IP interfaces. [type Ctrl-C to abort "Set Up"]

1. Enter **y** if you will be configuring VLANs. Otherwise enter **n**.

If you decide not to configure VLANs during this session, you can configure them later using the configuration menus, or by restarting the Setup facility. For more information on configuring VLANs, see the *Lenovo Networking OS Application Guide*.

Next, the Setup utility prompts you to input basic system information.

2. Enter the year of the current date at the prompt:

System Date:
Enter year [2009]:

Enter the four-digits that represent the year. To keep the current year, press <Enter>.

3. Enter the month of the current system date at the prompt:

System Date:
Enter month [1]:

Enter the month as a number from 1 to 12. To keep the current month, press <Enter>.

4. Enter the day of the current date at the prompt:

Enter day [3]:

Enter the date as a number from 1 to 31. To keep the current day, press <Enter>.

The system displays the date and time settings:

System clock set to 18:55:36 Wed Jan 28, 2009.

5. Enter the hour of the current system time at the prompt:

System Time:
Enter hour in 24-hour format [18]:

Enter the hour as a number from 00 to 23. To keep the current hour, press <Enter>.

6. Enter the minute of the current time at the prompt:

Enter minutes [55]:

Enter the minute as a number from 00 to 59. To keep the current minute, press <Enter>.

7. Enter the seconds of the current time at the prompt:

```
Enter seconds [37]:
```

Enter the seconds as a number from 00 to 59. To keep the current second, press <Enter>. The system then displays the date and time settings:

```
System clock set to 8:55:36 Wed Jan 28, 2009.
```

8. Turn Spanning Tree Protocol on or off at the prompt:

```
Spanning Tree:  
Current Spanning Tree Group 1 setting: ON  
Turn Spanning Tree Group 1 OFF? [y/n]
```

Enter **y** to turn off Spanning Tree, or enter **n** to leave Spanning Tree on.

Setup Part 2: Port Configuration

Note: When configuring port options for your switch, some prompts and options may be different.

1. Select whether you will configure VLANs and VLAN trunk mode/tagging for ports:

```
Port Config:
Will you configure VLANs and VLAN Tagging/Trunk-Mode for ports? [y/n]
```

If you wish to change settings for VLANs, enter **y**, or enter **n** to skip VLAN configuration.

Note: The sample screens that appear in this document might differ slightly from the screens displayed by your system. Screen content varies based on the firmware versions and options that are installed.

2. Select the port to configure, or skip port configuration at the prompt:

If you wish to change settings for individual ports, enter the number of the port you wish to configure. To skip port configuration, press <Enter> without specifying any port and go to [“Setup Part 3: VLANs” on page 56](#).

3. Configure Gigabit Ethernet port flow parameters.

The system prompts:

```
Gig Link Configuration:
Port Flow Control:
Current Port EXT1 flow control setting:    both
Enter new value ["rx"/"tx"/"both"/"none"]:
```

Enter **rx** to enable receive flow control, **tx** for transmit flow control, **both** to enable both, or **none** to turn flow control off for the port. To keep the current setting, press <Enter>.

4. Configure Gigabit Ethernet port autonegotiation mode.

If you selected a port that has a Gigabit Ethernet connector, the system prompts:

```
Port Auto Negotiation:
Current Port EXT1 autonegotiation:        on
Enter new value ["on"/"off"]:
```

Enter **on** to enable port autonegotiation, **off** to disable it, or press <Enter> to keep the current setting.

5. If configuring VLANs, enable or disable VLAN trunk mode/tagging for the port.

If you have selected to configure VLANs back in Part 1, the system prompts:

```
Port VLAN tagging/trunk mode config (tagged/trunk mode port can be a member
of multiple VLANs)
Current VLAN tagging/trunk mode support:    disabled
Enter new VLAN tagging/trunk mode support [d/e]:
```

Enter **d** to disable VLAN trunk mode/tagging for the port or enter **e** to enable VLAN tagging for the port. To keep the current setting, press <Enter>.

6. The system prompts you to configure the next port:

Enter port (1-65):

When you are through configuring ports, press <Enter> without specifying any port. Otherwise, repeat the steps in this section.

Setup Part 3: VLANs

If you chose to skip VLANs configuration back in Part 2, skip to [“Setup Part 4: IP Configuration” on page 57](#).

1. Select the VLAN to configure, or skip VLAN configuration at the prompt:

```
VLAN Config:
Enter VLAN number from 2 to 4094, NULL at end:
```

If you wish to change settings for individual VLANs, enter the number of the VLAN you wish to configure. To skip VLAN configuration, press <Enter> without typing a VLAN number and go to [“Setup Part 4: IP Configuration” on page 57](#).

2. Enter the new VLAN name at the prompt:

```
Current VLAN name: VLAN 2
Enter new VLAN name:
```

Entering a new VLAN name is optional. To use the pending new VLAN name, press <Enter>.

3. Enter the VLAN port numbers:

```
Define Ports in VLAN:
Current VLAN 2: empty
Enter ports one per line, NULL at end:
```

Enter each port, by port number or port alias, and confirm placement of the port into this VLAN. When you are finished adding ports to this VLAN, press <Enter> without specifying any port.

4. Configure Spanning Tree Group membership for the VLAN:

```
Spanning Tree Group membership:
Enter new Spanning Tree Group index [1-127]:
```

5. The system prompts you to configure the next VLAN:

```
VLAN Config:
Enter VLAN number from 2 to 4094, NULL at end:
```

Repeat the steps in this section until all VLANs have been configured. When all VLANs have been configured, press <Enter> without specifying any VLAN.

Setup Part 4: IP Configuration

The system prompts for IPv4 parameters.

Although the switch supports both IPv4 and IPv6 networks, the Setup utility permits only IPv4 configuration. For IPv6 configuration, see [“Internet Protocol Version 6” on page 323](#).

IP Interfaces

IP interfaces are used for defining the networks to which the switch belongs.

Up to 126 IP interfaces can be configured on the RackSwitch G8264CS (G8264CS). The IP address assigned to each IP interface provides the switch with an IP presence on your network. No two IP interfaces can be on the same IP network. The interfaces can be used for connecting to the switch for remote configuration, and for routing between subnets and VLANs (if used).

Note: IP interface 128 is reserved for out-of-band switch management.

1. Select the IP interface to configure, or skip interface configuration at the prompt:

```
IP Config:
IP interfaces:
Enter interface number: (1-126)
```

If you wish to configure individual IP interfaces, enter the number of the IP interface you wish to configure. To skip IP interface configuration, press <Enter> without typing an interface number and go to [“Default Gateways” on page 59](#).

2. For the specified IP interface, enter the IP address in IPv4 dotted decimal notation:

```
Current IP address:    0.0.0.0
Enter new IP address:
```

To keep the current setting, press <Enter>.

3. At the prompt, enter the IPv4 subnet mask in dotted decimal notation:

```
Current subnet mask:    0.0.0.0
Enter new subnet mask:
```

To keep the current setting, press <Enter>. If configuring VLANs, specify a VLAN for the interface.

This prompt appears if you selected to configure VLANs back in Part 1:

```
Current VLAN:    1
Enter new VLAN [1-4094]:
```

Enter the number for the VLAN to which the interface belongs, or press <Enter> without specifying a VLAN number to accept the current setting.

4. At the prompt, enter **y** to enable the IP interface, or **n** to leave it disabled:

```
Enable IP interface? [y/n]
```

5. The system prompts you to configure another interface:

```
Enter interface number: (1-126)
```

Repeat the steps in this section until all IP interfaces have been configured. When all interfaces have been configured, press <Enter> without specifying any interface number.

Loopback Interfaces

A loopback interface provides an IP address, but is not otherwise associated with a physical port or network entity. Essentially, it is a virtual interface that is perceived as being “always available” for higher-layer protocols to use and advertise to the network, regardless of other connectivity.

Loopback interfaces improve switch access, increase reliability, security, and provide greater flexibility in Layer 3 network designs. They can be used for many different purposes, but are most commonly for management IP addresses, router IDs for various protocols, and persistent peer IDs for neighbor relationships.

In Lenovo N/OS 8.2, loopback interfaces have been expanded for use with routing protocols such as OSPF, PIM, and BGP. Loopback interfaces can also be specified as the source IP address for syslog, SNMP, RADIUS, TACACS+, NTP, and router IDs.

Loopback interfaces must be configured before they can be used in other features. Up to five loopback interfaces are currently supported. They can be configured using the following commands:

```
RS 8264CS(config)# interface loopback <1-5>  
RS 8264CS(config-ip-loopback)# [no] ip address <IPv4 address> <mask> enable  
RS 8264CS(config-ip-loopback)# exit
```

Using Loopback Interfaces for Source IP Addresses

The switch can use loopback interfaces to set the source IP addresses for a variety of protocols. This assists in server security, as the server for each protocol can be configured to accept protocol packets only from the expected loopback address block. It may also make it easier to locate or process protocol information, since packets have the source IP address of the loopback interface, rather than numerous egress interfaces.

Configured loopback interfaces can be applied to the following protocols:

- Syslogs

```
RS 8264CS(config)# logging source-interface loopback <1-5>
```

- SNMP traps

```
RS 8264CS(config)# snmp-server trap-source loopback <1-5>
```

- RADIUS

```
RS 8264CS(config)# ip radius source-interface loopback <1-5>
```

- TACACS+

```
RS 8264CS(config)# ip tacacs source-interface loopback <1-5>
```

- NTP

```
RS 8264CS(config)# ntp source loopback <1-5>
```

Loopback Interface Limitation

- ARP is not supported. Loopback interfaces will ignore ARP requests.
- Loopback interfaces cannot be assigned to a VLAN.

Default Gateways

To set up a default gateway:

1. At the prompt, select an IP default gateway for configuration, or skip default gateway configuration:

```
IP default gateways:
Enter default gateway number: (1-4)
```

Enter the number for the IP default gateway to be configured. To skip default gateway configuration, press <Enter> without typing a gateway number and go to [“IP Routing” on page 59](#).

2. At the prompt, enter the IPv4 address for the selected default gateway:

```
Current IP address:    0.0.0.0
Enter new IP address:
```

Enter the IPv4 address in dotted decimal notation, or press <Enter> without specifying an address to accept the current setting.

3. At the prompt, enter **y** to enable the default gateway, or **n** to leave it disabled:

```
Enable default gateway? [y/n]
```

4. The system prompts you to configure another default gateway:

```
Enter default gateway number: (1-4)
```

Repeat the steps in this section until all default gateways have been configured. When all default gateways have been configured, press <Enter> without specifying any number.

IP Routing

When IP interfaces are configured for the various IP subnets attached to your switch, IP routing between them can be performed entirely within the switch. This eliminates the need to send inter-subnet communication to an external router

device. Routing on more complex networks, where subnets may not have a direct presence on the G8264CS, can be accomplished through configuring static routes or by letting the switch learn routes dynamically.

This part of the Setup program prompts you to configure the various routing parameters.

At the prompt, enable or disable forwarding for IP Routing:

Enable IP forwarding? [y/n]

Enter **y** to enable IP forwarding. To disable IP forwarding, enter **n**. To keep the current setting, press <Enter>.

Setup Part 5: Final Steps

1. When prompted, decide whether to restart Setup or continue:

Would you like to run from top again? [y/n]

Enter **y** to restart the Setup utility from the beginning, or **n** to continue.

2. When prompted, decide whether you wish to review the configuration changes:

Review the changes made? [y/n]

Enter **y** to review the changes made during this session of the Setup utility. Enter **n** to continue without reviewing the changes. We recommend that you review the changes.

3. Next, decide whether to apply the changes at the prompt:

Apply the changes? [y/n]

Enter **y** to apply the changes, or **n** to continue without applying. Changes are normally applied.

4. At the prompt, decide whether to make the changes permanent:

Save changes to flash? [y/n]

Enter **y** to save the changes to flash. Enter **n** to continue without saving the changes. Changes are normally saved at this point.

5. If you do not apply or save the changes, the system prompts whether to abort them:

Abort all changes? [y/n]

Enter **y** to discard the changes. Enter **n** to return to the "Apply the changes?" prompt.

Note: After initial configuration is complete, it is recommended that you change the default passwords.

Optional Setup for Telnet Support

Note: This step is optional. Perform this procedure only if you are planning on connecting to the G8264CS through a remote Telnet connection.

Telnet is enabled by default. To change the setting, use the following command:

```
RS 8264CS(config)# no access telnet
```

Chapter 3. Service Location Protocol

Service Location Protocol (SLP) allows the switch to provide dynamic directory services that help users find servers by attributes rather than by name or address. SLP eliminates the need for a user to know the name of a network host supporting a service. SLP allows the user to bind a service description to the network address of the service.

Service Location Protocol is described in RFC 2608.

SLP defines specialized components called agents that perform tasks and support services as follows:

- User Agent (UA) supports service query functions. It requests service information for user applications. The User Agent retrieves service information from the Service Agent or Directory Agents. A Host On-Demand client is an example of a User Agent.
- Service Agent (SA) provides service registration and service advertisement.
Note: In this release, SA supports UA/DA on Linux with SLPv2 support.
- Directory Agent (DA) collects service information from Service Agents to provide a repository of service information in order to centralize it for efficient access by User Agents. There can only be one Directory Agent present per given host.

The Directory Agent acts as an intermediate tier in the SLP architecture, placed between the User Agents and the Service Agents, so they communicate only with the Directory Agent instead of with each other. This eliminates a large portion of the multicast request or reply traffic on the network, and it protects the Service Agents from being overwhelmed by too many service requests.

Services are described by the configuration of attributes associated with a type of service. A User Agent can select an appropriate service by specifying the attributes that it needs in a service request message. When service replies are returned, they contain a Uniform Resource Locator (URL) pointing to the service desired, and other information, such as server load, needed by the User Agent.

Active DA Discovery

When a Service Agent or User Agent initializes, it can perform Active Directory Agent Discovery using a multicast service request and specifies the special, reserved service type (`service:directory-agent`). Active DA Discovery is achieved through the same mechanism as any other discovery using SLP.

The Directory Agent replies with unicast service replies, which provides the URLs and attributes of the requested service.

SLP Configuration

Use the following ISCLI commands to configure SLP for the switch:

Table 6. *SLP ISCLI Commands*

Command Syntax and Usage
<pre>[no] ip slp enable</pre> <p>Enables or disables SLP on the switch. Command mode: Global configuration</p>
<pre>[no] ip slp active-da-discovery enable</pre> <p>Enables or disables Active DA Discovery. Command mode: Global configuration</p>
<pre>clear ip slp directory-agents</pre> <p>Clears all Directory Agents learned by the switch. Command mode: Global configuration</p>

Chapter 4. Switch Software Management

The switch software image is the executable code running on the G8264CS. A version of the image comes pre-installed on the device. As new versions of the image are released, you can upgrade the software running on your switch. To get the latest version of software supported for your G8264CS, go to the following website:

<http://www.lenovo.com/support/>

To determine the software version currently used on the switch, use the following switch command:

```
RS 8264CS# show boot
```

The typical upgrade process for the software image consists of the following steps:

- Load a new software image and boot image onto an FTP, SFTP, or TFTP server on your network.
- Transfer the new images to your switch.
- Specify the new software image as the one which will be loaded into switch memory the next time a switch reset occurs.
- Reset the switch.

For instructions on the typical upgrade process, see “[Loading New Software to Your Switch](#)” on page 66.

CAUTION:

Although the typical upgrade process is all that is necessary in most cases, upgrading from (or reverting to) some versions of Lenovo Networking OS requires special steps prior to or after the software installation process. Please be sure to follow all applicable instructions in the release notes document for the specific software release to ensure that your switch continues to operate as expected after installing new software.

Loading New Software to Your Switch

The G8264CS can store up to two different switch software images (called `image1` and `image2`) as well as special boot software (called `boot`). When you load new software, you must specify where it is placed: either into `image1`, `image2`, or `boot`.

For example, if your active image is currently loaded into `image1`, you would probably load the new image software into `image2`. This lets you test the new software and reload the original active image (stored in `image1`), if needed.

CAUTION:

When you upgrade the switch software image, always load the new boot image and the new software image before you reset the switch. If you do not load a new boot image, your switch might not boot properly (To recover, see [“Recovering from a Failed Software Upgrade”](#) on page 71).

To load a new software image to your switch, you will need the following:

- The image and boot software loaded on an FTP, SFTP, or TFTP server on your network.

Note: Be sure to download both the new boot file and the new image file.

- The hostname or IP address of the FTP, SFTP, or TFTP server

Note: The DNS parameters must be configured if specifying hostnames.

- The name of the new software image or boot file

After you have successfully loaded the new software image, the message “Valid image detected” is displayed, ensuring that the software image has been received from the trusted source.

Note: If the message “Failure: image contains invalid signature” is displayed while the new image is loading, the software image does not have a valid security signature for the switch. In this case, make sure you have downloaded the correct image from an authenticated source.

When the software requirements are met, use one of the following procedures to download the new software to your switch. You can use the ISCLI, USB, or the BBI to download and activate new software.

Loading Software via the ISCLI

1. In Privileged EXEC mode, enter the following command:

```
Router# copy {sftp|tftp|ftp} {image1|image2|boot-image}
```

2. Enter the hostname or IP address of the FTP, SFTP, or TFTP server.

```
Address or name of remote host: <name or IP address>
```

3. Enter the name of the new software file on the server.

```
Source file name: <filename>
```

The exact form of the name will vary by server. However, the file location is normally relative to the FTP, SFTP, or TFTP directory (for example, `tftpboot`).

4. If required by the FTP, SFTP, or TFTP server, enter the appropriate username and password.
5. The switch will prompt you to confirm your request.

Once confirmed, the software will begin loading into the switch.

6. When loading is complete, use the following commands to enter Global Configuration mode to select which software image (`image1` or `image2`) you want to run in switch memory for the next reboot:

```
Router# configure terminal  
Router(config)# boot image {image1|image2}
```

The system will then verify which image is set to be loaded at the next reset:

```
Next boot will use switch software image1 instead of image2.
```

7. Reboot the switch to run the new software:

```
Router(config)# reload
```

The system prompts you to confirm your request. Once confirmed, the switch will reboot to use the new software.

Loading Software via BBI

You can use the Browser-Based Interface to load software onto the G8264CS. The software image to load can reside in one of the following locations:

- FTP server
- SFTP server
- TFTP server
- Local computer

After you log onto the BBI, perform the following steps to load a software image:

1. Click the Configure context tab in the toolbar.
2. In the Navigation Window, select System > Config/Image Control.

The Switch Image and Configuration Management page appears.

3. If you are loading software from your computer (HTTP client), skip this step and go to the next. Otherwise, if you are loading software from an FTP, SFTP, or TFTP server, enter the server's information in the FTP, SFTP, or TFTP Settings section.
4. In the Image Settings section, select the image version you want to replace (Image for Transfer).

- If you are loading software from an FTP, SFTP, or TFTP server, enter the file name and click **Get Image**.
- If you are loading software from your computer, click **Browse**.

In the File Upload Dialog, select the file and click **OK**. Then click **Download via Browser**.

Once the image has loaded, the page refreshes to show the new software.

USB Options

You can insert a USB drive into the USB port on the G8264CS and use it to work with switch image and configuration files. You can boot the switch using files located on the USB drive, or copy files to and from the USB drive.

To safely remove the USB drive, first use the following command to un-mount the USB file system:

system usb-eject

Command mode: Global configuration

USB Boot

USB Boot allows you to boot the switch with a software image file, boot file, or configuration file that resides on a USB drive inserted into the USB port. Use the following command to enable or disable USB Boot:

[no] boot usbboot enable

Command mode: Global configuration

When enabled, when the switch is reset/reloaded, it checks the USB port. If a USB drive is inserted into the port, the switch checks the root directory on the USB drive for software and image files. If a valid file is present, the switch loads the file and boots using the file.

Note: The following file types are supported: FAT32, NTFS (read-only), EXT2, and EXT3.

The following list describes the valid file names, and describes the switch behavior when it recognizes them. The file names must be exactly as shown, or the switch will not recognize them.

- **RS8264CS_Boot .img**
The switch replaces the current boot image with the new image, and boots with the new image.
- **RS8264CS_OS .img**
The switch boots with the new software image. The existing images are not affected.
- **RS8264CS_replace1_OS .img**
The switch replaces the current software image1 with the new image, and boots with the new image. **RS8264CS_replace1_OS .img** takes precedence over **RS8264CS_OS .img**

- **RS8264CS_replace2_OS.img**
The switch replaces the current software image2 with the new image, and boots with the new image. RS8264CS_replace2_OS.img takes precedence over RS8264CS_OS.img
- **RS8264CS.cfg**
The switch boots with the new configuration file. The existing configuration files (active and backup) are not affected.
- **RS8264CS_replace.cfg**
The switch replaces the active configuration file with the new file, and boots with the new file. This file takes precedence over any other configuration files that may be present on the USB drive.

If more than one valid file is present, the switch loads all valid files and boots with them. For example, you may simultaneously load a new boot file, image file, and configuration file from the USB drive.

The switch ignores any files that do not match the valid file names or that have the wrong format.

USB Copy

If a USB drive is inserted into the USB port, you can copy files from the switch to the USB drive, or from the USB drive to the switch. USB Copy is available only for software image 1 and the active configuration.

Copy to USB

Use the following command to copy a file from the switch to the USB drive (Privileged EXEC mode):

```
usbcopy tousb <filename> {boot|image1|active|syslog|crashdump}
```

In this example, the active configuration file is copied to a directory on the USB drive:

```
G8264CS(config)# usbcopy tousb a_folder/myconfig.cfg active
```

Copy from USB

Use the following command to copy a file from the USB drive to the switch:

```
usbcopy fromusb <filename> {boot|image1|active}
```

In this example, the active configuration file is copied from a directory on the USB drive:

```
G8264CS(config)# usbcopy fromusb a_folder/myconfig.cfg active
```

The new file replaces the current file.

Note: Do not use two consecutive dot characters (..). Do not use a slash character (/) to begin a filename.

The Boot Management Menu

The Boot Management menu allows you to switch the software image, reset the switch to factory defaults, or to recover from a failed software download.

You can interrupt the boot process and enter the Boot Management menu from the serial console port. When the system displays Memory Test, press **<Shift B>**. The Boot Management menu appears.

```
U-Boot 2009.06 (Feb 26 2015 - 06:40:23)

CPU: 8536, Version: 1.2, (0x80370092)
Core: E500, Version: 3.0, (0x80210030)

Boot Management Menu
  I - Change booting image
  C - Change configuration block
  R - Boot in recovery mode (tftp and xmodem download of images to
recover switch)
  Q - Reboot
  E - Exit
Please choose your menu option: R
```

The Boot Management menu allows you to perform the following actions:

- To change the booting image, press I and follow the screen prompts.
- To change the configuration block, press C and follow the screen prompts.
- To perform a software image recovery, press R and follow the screen prompts.
- To reboot the switch press Q and follow the screen prompts.
- To exit the Boot Management menu, press E. The booting process continues.

Recovering from a Failed Software Upgrade

Use the following procedure to recover from a failed software upgrade.

1. Connect a PC to the serial port of the switch.
2. Open a terminal emulator program that supports Xmodem download (for example, HyperTerminal, CRT, PuTTY) and select the following serial port characteristics:
 - Speed: 9600 bps
 - Data Bits: 8
 - Stop Bits: 1
 - Parity: None
 - Flow Control: None
3. Boot the switch and access the Boot Management menu by pressing **<Shift B>** while the Memory Test is in progress and the dots are being displayed.
4. Select **R** for **Boot in recovery mode**. You will see the following display:

```
Entering Rescue Mode.
Please select one of the following options:
    T) Configure networking and tftp download an image
    X) Use xmodem 1K to serial download an image
    P) Physical presence (low security mode)
    R) Reboot
    E) Exit

Option?:
```

- If you choose option **X** (Xmodem serial download), go to step 5.
- If you choose option **T** (TFTP download), go to step 6.

5. **Xmodem download:** When you see the following message, change the Serial Port characteristics to 115200 bps:

```
Change the baud rate to 115200 bps and hit the <ENTER> key before
initiating the download.
```

- a. Press <Enter> to set the system into download accept mode. When the readiness meter displays (a series of "C" characters), start XModem on your terminal emulator.
- b. When you see the following message, change the Serial Port characteristics to 9600 bps:

```
Change the baud rate back to 9600 bps, hit the <ESC> key.
```

- c. When you see the following prompt, enter the image number where you want to install the new software and press <Enter>.

```
Install image as image 1 or 2 (hit return to just boot image): 1
```

- d. The following message is displayed when the image download is complete. Continue to step 7.

```
Installing image as image1...
Image1 updated successfully
Please select one of the following options:
  T) Configure networking and tftp download an image
  X) Use xmodem 1K to serial download an image
  P) Physical presence (low security mode)
  R) Reboot
  E) Exit
```

6. **TFTP download:** The switch prompts you to enter the following information:

```
Performing TFTP rescue. Please answer the following questions (enter 'q'
to quit):
IP addr   :
Server addr:
Netmask   :
Gateway   :
Image Filename:
```

- a. Enter the required information and press **<Enter>**.
- b. You will see a display similar to the following:

```
Host IP    : 10.10.98.110
Server IP  : 10.10.98.100
Netmask    : 255.255.255.0
Broadcast  : 10.10.98.255
Gateway    : 10.10.98.254
Installing image 6.8.3_OS.img from TFTP server 10.10.98.100
```

- c. When you see the following prompt, enter the image number where you want to install the new software and press **<Enter>**.

```
Install image as image 1 or 2 (hit return to just boot image): 1
```

- d. The following message is displayed when the image download is complete. Continue to step 7.

```
Installing image as image1...
Image1 updated successfully
Please select one of the following options:
  T) Configure networking and tftp download an image
  X) Use xmodem 1K to serial download an image
  P) Physical presence (low security mode)
  R) Reboot
  E) Exit
```

7. Image recovery is complete. Perform one of the following steps:
 - Press **r** to reboot the switch.
 - Press **e** to exit the Boot Management menu
 - Press the Escape key (**<Esc>**) to re-display the Boot Management menu.

Recovering a Failed Boot Image

Use the following procedure to recover from a failed boot image upgrade.

1. Connect a PC to the serial port of the switch.
2. Open a terminal emulator program that supports Xmodem download (for example, HyperTerminal, CRT, PuTTY) and select the following serial port characteristics:
 - Speed: 9600 bps

- Data Bits: 8
- Stop Bits: 1
- Parity: None
- Flow Control: None

3. Boot the switch and access the Boot Management menu by pressing **<Shift B>** while the Memory Test is in progress and the dots are being displayed.
4. Press **R** for Boot in Recovery Mode, then press **X** for **Xmodem download**. You will see the following display:

```
Perform xmodem download

To download an image use 1K Xmodem at 115200 bps.
```

5. When you see the following message, change the Serial Port characteristics to 115200 bps:

```
Change the baud rate to 115200 bps and hit the <ENTER> key before
initiating the download.
```

- a. Press **<Enter>** to set the system into download accept mode. When the readiness meter displays (a series of "C" characters), start Xmodem on your terminal emulator. You will see a display similar to the following:

```
Extracting images ... Do *NOT* power cycle the switch.
**** RAMDISK ****
Un-Protected 38 sectors
Erasing Flash...
..... done
Erased 38 sectors
Writing to Flash...9...8...7...6...5...4...3...2...1...done
Protected 38 sectors
**** KERNEL ****
Un-Protected 24 sectors
Erasing Flash...
..... done
Erased 24 sectors
Writing to Flash...9...8...7...6...5...4...3...2...1...
```

- b. When you see the following message, change the Serial Port characteristics to 9600 bps:

```
Change the baud rate back to 9600 bps, hit the <ESC> key.
```

Boot image recovery is complete.

Part 2: Securing the Switch

Chapter 5. Securing Administration

Secure switch management is needed for environments that perform significant management functions across the Internet. Common functions for secured management are described in the following sections:

- [“Secure Shell and Secure Copy” on page 78](#)
- [“End User Access Control” on page 82](#)

Note: SNMP read and write functions are enabled by default. For best security practices, if SNMP is not needed for your network, it is recommended that you disable these functions prior to connecting the switch to the network (see [“Using Simple Network Management Protocol” on page 36](#)).

Secure Shell and Secure Copy

Because using Telnet does not provide a secure connection for managing a G8264CS, Secure Shell (SSH) and Secure Copy (SCP) features have been included for G8264CS management. SSH and SCP use secure tunnels to encrypt and secure messages between a remote administrator and the switch.

SSH is a protocol that enables remote administrators to log securely into the G8264CS over a network to execute management commands.

SCP is typically used to copy files securely from one machine to another. SCP uses SSH for encryption of data on the network. On a G8264CS, SCP is used to download and upload the switch configuration via secure channels.

Although SSH and SCP are disabled by default, enabling and using these features provides the following benefits:

- Identifying the administrator using Name/Password
- Authentication of remote administrators
- Authorization of remote administrators
- Determining the permitted actions and customizing service for individual administrators
- Encryption of management messages
- Encrypting messages between the remote administrator and switch
- Secure copy support

Lenovo Networking OS implements the SSH version 2.0 standard and is confirmed to work with SSH version 2.0-compliant clients such as the following:

- OpenSSH_5.4p1 for Linux
- Secure CRT Version 5.0.2 (build 1021)
- Putty SSH release 0.60

Configuring SSH/SCP Features on the Switch

SSH and SCP features are disabled by default. To change the SSH/SCP settings, using the following procedures.

Note: To use SCP, you must first enable SSH.

To Enable or Disable the SSH Feature

Connect to the console port and enter the following command:

```
RS 8264CS(config)# [no] ssh enable
```

To Enable or Disable SCP Apply and Save

Enter the following command from the switch CLI to enable the SCP `putcfg_apply` and `putcfg_apply_save` commands:

```
RS 8264CS(config)# [no] ssh scp-enable
```

Configuring the SCP Administrator Password

To configure the SCP-only administrator password, enter the following command (the default password is admin):

```
RS 8264CS(config)# [no] ssh scp-password
Changing SCP-only Administrator password; validation required...
Enter current administrator password: <password>
Enter new SCP-only administrator password: <new password>
Re-enter new SCP-only administrator password: <new password>
New SCP-only administrator password accepted.
```

Using SSH and SCP Client Commands

This section shows the format for using some client commands. The following examples use 205.178.15.157 as the IP address of a sample switch.

To Log In to the Switch

Syntax:

```
>> ssh [-4|-6] <switch IP address>
-or-
>> ssh [-4|-6] <login name>@<switch IP address>
```

Note: The -4 option (the default) specifies that an IPv4 switch address will be used. The -6 option specifies IPv6.

Example:

```
>> ssh scpadmin@205.178.15.157
```

To Copy the Switch Configuration File to the SCP Host

Syntax:

```
>> scp [-4|-6] <username>@<switch IP address>:getcfg <local filename>
```

Example:

```
>> scp scpadmin@205.178.15.157:getcfg ad4.cfg
```

To Load a Switch Configuration File from the SCP Host

Syntax:

```
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putcfg
```

Example:

```
>> scp ad4.cfg scpadmin@205.178.15.157:putcfg
```

To Apply and Save the Configuration

When loading a configuration file to the switch, the `apply` and `save` commands are still required for the configuration commands to take effect. The `apply` and `save` commands may be entered manually on the switch, or by using SCP commands.

Syntax:

```
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putcfg_apply
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putcfg_apply_save
```

Example:

```
>> scp ad4.cfg scpadmin@205.178.15.157:putcfg_apply
>> scp ad4.cfg scpadmin@205.178.15.157:putcfg_apply_save
```

- The CLI `diff` command is automatically executed at the end of `putcfg` to notify the remote client of the difference between the new and the current configurations.
- `putcfg_apply` runs the `apply` command after the `putcfg` is done.
- `putcfg_apply_save` saves the new configuration to the flash after `putcfg_apply` is done.
- The `putcfg_apply` and `putcfg_apply_save` commands are provided because extra `apply` and `save` commands are usually required after a `putcfg`; however, an SCP session is not in an interactive mode.

To Copy the Switch Image and Boot Files to the SCP Host

Syntax:

```
>> scp [-4|-6] <username>@<switch IP address>:getimg1 <local filename>
>> scp [-4|-6] <username>@<switch IP address>:getimg2 <local filename>
>> scp [-4|-6] <username>@<switch IP address>:getboot <local filename>
```

Example:

```
>> scp scpadmin@205.178.15.157:getimg1 6.1.0_os.img
```

To Load Switch Configuration Files from the SCP Host

Syntax:

```
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putimg1
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putimg2
>> scp [-4|-6] <local filename> <username>@<switch IP address>:putboot
```

Example:

```
>> scp 6.1.0_os.img scpadmin@205.178.15.157:putimg1
```

SSH and SCP Encryption of Management Messages

The following encryption and authentication methods are supported for SSH and SCP:

- Server Host Authentication: Client RSA authenticates the switch at the beginning of every connection
- Key Exchange: RSA
- Encryption: 3DES-CBC
- User Authentication: Local password authentication, RADIUS

Generating RSA Host Key for SSH Access

To support the SSH host feature, an RSA host key is required. The host key is 2048 bits and is used to identify the G8264CS.

To configure RSA host key, first connect to the G8264CS through the console port (commands are not available via external Telnet connection), and enter the following command to generate it manually.

```
RS 8264CS(config)# ssh generate-host-key
```

When the switch reboots, it will retrieve the host key from the FLASH memory.

Note: The switch will perform only one session of key/cipher generation at a time. Thus, an SSH/SCP client will not be able to log in if the switch is performing key generation at that time. Also, key generation will fail if an SSH/SCP client is logging in at that time.

SSH/SCP Integration with Radius Authentication

SSH/SCP is integrated with RADIUS authentication. After the RADIUS server is enabled on the switch, all subsequent SSH authentication requests will be redirected to the specified RADIUS servers for authentication. The redirection is transparent to the SSH clients.

SSH/SCP Integration with TACACS+ Authentication

SSH/SCP is integrated with TACACS+ authentication. After the TACACS+ server is enabled on the switch, all subsequent SSH authentication requests will be redirected to the specified TACACS+ servers for authentication. The redirection is transparent to the SSH clients.

End User Access Control

Lenovo N/OS allows an administrator to define end user accounts that permit end users to perform operation tasks via the switch CLI commands. Once end user accounts are configured and enabled, the switch requires username/password authentication.

For example, an administrator can assign a user, who can then log into the switch and perform operational commands (effective only until the next switch reboot).

Considerations for Configuring End User Accounts

Note the following considerations when you configure end user accounts:

- A maximum of 20 user IDs are supported on the switch.
- N/OS supports end user support for console, Telnet, BBI, and SSHv2 access to the switch.
- If RADIUS authentication is used, the user password on the Radius server will override the user password on the G8264CS. Also note that the password change command only modifies only the user password on the switch and has no effect on the user password on the Radius server. Radius authentication and user password cannot be used concurrently to access the switch.
- Passwords for end users can be up to 128 characters in length for TACACS, RADIUS, Telnet, SSH, Console, and Web access.

Strong Passwords

The administrator can require use of Strong Passwords for users to access the G8264CS. Strong Passwords enhance security because they make password guessing more difficult.

The following rules apply when Strong Passwords are enabled:

- Minimum length: 8 characters; maximum length: 64 characters.
- Must contain at least one uppercase alphabet.
- Must contain at least one lowercase alphabet.
- Must contain at least one number.
- Must contain at least one special character.
Supported special characters: ! " # % & ' () ; < = > ? [\] * + , - . / : ^ _ { | } ~
- Cannot be same as the username.
- No consecutive four characters can be the same as in the old password.

When strong password is enabled, users can still access the switch using the old password but will be advised to change to a strong password while attempting to log in.

Strong password requirement can be enabled using the following command:

```
RS 8264CS(config)# access user strong-password enable
```

The administrator can choose the number of days allowed before each password expires. When a strong password expires, the user is allowed to log in one last time to change the password. A warning provides advance notice for users to change the password.

User Access Control

The end-user access control commands allow you to configure end-user accounts.

Setting up User IDs

Up to 20 user IDs can be configured. Use the following commands to define any user name and set the user password at the resulting prompts:

```
RS 8264CS(config)# access user 1 name <1-8 characters>
RS 8264CS(config)# access user 1 password

Changing user1 password; validation required:
Enter current admin password: <current administrator password>
Enter new user1 password: <new user password>
Re-enter new user1 password: <new user password>
New user1 password accepted.
```

Defining a User's Access Level

The end user is by default assigned to the user access level (also known as class of service, or COS). COS for all user accounts have global access to all resources except for User COS, which has access to view only resources that the user owns. For more information, see [Table 7 on page 88](#).

To change the user's level, select one of the following options:

```
RS 8264CS(config)# access user 1 level {user|operator|administrator}
```

Validating a User's Configuration

```
RS 8264CS# show access user uid 1
```

Enabling or Disabling a User

An end user account must be enabled before the switch recognizes and permits login under the account. Once enabled, the switch requires any user to enter both username and password.

```
RS 8264CS(config)# [no] access user 1 enable
```

Locking Accounts

To protect the switch from unauthorized access, the account lockout feature can be enabled. By default, account lockout is disabled. To enable this feature, ensure the strong password feature is enabled (*See "Strong Passwords" on page 82*). Then use the following command:

```
RS 8264CS(config)# access user strong-password lockout
```

After multiple failed login attempts, the switch locks the user account if lockout has been enabled on the switch.

Re-enabling Locked Accounts

The administrator can re-enable a locked account by reloading the switch or by using the following command:

```
RS 8264CS(config)# access user strong-password clear local user lockout
username <user name>
```

However, the above command cannot be used to re-enable an account disabled by the administrator.

To re-enable all locked accounts, use the following command:

```
RS 8264CS(config)# access user strong-password clear local user lockout
all
```

Listing Current Users

The following command displays defined user accounts and whether or not each user is currently logged into the switch.

```
RS 8264CS# show access user

Usernames:
  user      - Enabled - offline
  oper      - Disabled - offline
  admin     - Always Enabled - online 1 session

Current User ID table:
1: name jane   , ena, cos user   , password valid, online 1 session
2: name john   , ena, cos user   , password valid, online 2 sessions
```

Logging into an End User Account

Once an end user account is configured and enabled, the user can login to the switch using the username/password combination. The level of switch access is determined by the COS established for the end user account.

Chapter 6. Authentication & Authorization Protocols

Secure switch management is needed for environments that perform significant management functions across the Internet. The following are some of the functions for secured IPv4 management and device access:

- [“RADIUS Authentication and Authorization” on page 86](#)
- [“TACACS+ Authentication” on page 90](#)
- [“LDAP Authentication and Authorization” on page 94](#)

Note: Lenovo Networking OS 8.2 does not support IPv6 for RADIUS, TACACS+, or LDAP.

RADIUS Authentication and Authorization

Lenovo N/OS supports the RADIUS (Remote Authentication Dial-in User Service) method to authenticate and authorize remote administrators for managing the switch. This method is based on a client/server model. The Remote Access Server (RAS)—the switch—is a client to the back-end database server. A remote user (the remote administrator) interacts only with the RAS, not the back-end server and database.

RADIUS authentication consists of the following components:

- A protocol with a frame format that utilizes UDP over IP (based on RFC 2138 and 2866)
- A centralized server that stores all the user authorization information
- A client: in this case, the switch

The G8264CS—acting as the RADIUS client—communicates to the RADIUS server to authenticate and authorize a remote administrator using the protocol definitions specified in RFC 2138 and 2866. Transactions between the client and the RADIUS server are authenticated using a shared key that is not sent over the network. In addition, the remote administrator passwords are sent encrypted between the RADIUS client (the switch) and the back-end RADIUS server.

How RADIUS Authentication Works

The RADIUS authentication process follows these steps:

1. A remote administrator connects to the switch and provides a user name and password.
2. Using Authentication/Authorization protocol, the switch sends request to authentication server.
3. The authentication server checks the request against the user ID database.
4. Using RADIUS protocol, the authentication server instructs the switch to grant or deny administrative access.

Configuring RADIUS on the Switch

Use the following procedure to configure Radius authentication on your switch.

1. Configure the IPv4 addresses of the Primary and Secondary RADIUS servers, and enable RADIUS authentication.

```
RS 8264CS(config)# radius-server primary-host 10.10.1.1
RS 8264CS(config)# radius-server secondary-host 10.10.1.2
RS 8264CS(config)# radius-server enable
```

Note: You can use a configured loopback address as the source address so the RADIUS server accepts requests only from the expected loopback address block. Use the following command to specify the loopback interface:

```
RS 8264CS(config)# ip radius source-interface loopback <1-5>
```

2. Configure the RADIUS secret.

```
RS 8264CS(config)# radius-server primary-host 10.10.1.1 key  
<1-32 character secret>  
RS 8264CS(config)# radius-server secondary-host 10.10.1.2 key  
<1-32 character secret>
```

3. If desired, you may change the default UDP port number used to listen to RADIUS.
The well-known port for RADIUS is 1812.

```
RS 8264CS(config)# radius-server port <UDP port number>
```

4. Configure the number retry attempts for contacting the RADIUS server, and the timeout period.

```
RS 8264CS(config)# radius-server retransmit 3  
RS 8264CS(config)# radius-server timeout 5
```

RADIUS Authentication Features in Lenovo N/OS

N/OS supports the following RADIUS authentication features:

- Supports RADIUS client on the switch, based on the protocol definitions in RFC 2138 and RFC 2866.
- Allows RADIUS secret password up to 32 bytes and less than 16 octets.
- Supports *secondary authentication server* so that when the primary authentication server is unreachable, the switch can send client authentication requests to the secondary authentication server. Use the following command to show the currently active RADIUS authentication server:

```
RS 8264CS# show radius-server
```

- Supports user-configurable RADIUS server retry and time-out values:
 - Time-out value = 1-10 seconds
 - Retries = 1-3

The switch will time out if it does not receive a response from the RADIUS server in 1-3 retries. The switch will also automatically retry connecting to the RADIUS server before it declares the server down.

- Supports user-configurable RADIUS application port. The default is UDP port 1645. UDP port 1812, based on RFC 2138, is also supported.
- Allows network administrator to define privileges for one or more specific users to access the switch at the RADIUS user database.

Switch User Accounts

The user accounts listed in [Table 7](#) can be defined in the RADIUS server dictionary file.

Table 7. *User Access Levels*

User Account	Description and Tasks Performed	Password
User	The User has no direct responsibility for switch management. They can view all switch status information and statistics but cannot make any configuration changes to the switch.	user
Operator	The Operator manages all functions of the switch. The Operator can reset ports, except the management port.	oper
Administrator	The super-user Administrator has complete access to all commands, information, and configuration commands on the switch, including the ability to change both the user and administrator passwords.	admin

RADIUS Attributes for Lenovo N/OS User Privileges

When the user logs in, the switch authenticates his/her level of access by sending the RADIUS access request, that is, the client authentication request, to the RADIUS authentication server.

If the remote user is successfully authenticated by the authentication server, the switch will verify the *privileges* of the remote user and authorize the appropriate access. The administrator has two options: to allow *backdoor* access via Telnet, SSH, HTTP, or HTTPS; to allow *secure backdoor* access via console, Telnet, SSH, or BBI. Backdoor provides access to the switch when the RADIUS servers cannot be reached.

The default G8264CS setting for backdoor and secure backdoor access is disabled. Backdoor access is always enabled on the console port.

Whether or not backdoor is enabled, you can always access the switch via the console port by using noradius as RADIUS username. You can then enter the username and password configured on the switch. If you are trying to connect via SSH/Telnet/HTTP/HTTPS, there are two possibilities:

- Backdoor is enabled: The switch acts like it is connecting via console.
- Secure backdoor is enabled: You must enter the username: noradius. The switch checks if RADIUS server is reachable. If it is reachable, then you must authenticate via remote authentication server. Only if RADIUS server is not reachable, you will be prompted for local user/password to be authenticated against these local credentials.

All user privileges, other than those assigned to the Administrator, have to be defined in the RADIUS dictionary. RADIUS attribute 6 which is built into all RADIUS servers defines the administrator. The file name of the dictionary is RADIUS vendor-dependent. The following RADIUS attributes are defined for G8264CS user privileges levels:

Table 8. *Lenovo N/OS-proprietary Attributes for RADIUS*

User Name/Access	User-Service-Type	Value
User	<i>Vendor-supplied</i>	255
Operator	<i>Vendor-supplied</i>	252
Admin	<i>Vendor-supplied</i>	6

TACACS+ Authentication

N/OS supports authentication and authorization with networks using the Cisco Systems TACACS+ protocol. The G8264CS functions as the Network Access Server (NAS) by interacting with the remote client and initiating authentication and authorization sessions with the TACACS+ access server. The remote user is defined as someone requiring management access to the G8264CS either through a data port or management port.

TACACS+ offers the following advantages over RADIUS:

- TACACS+ uses TCP-based connection-oriented transport; whereas RADIUS is UDP-based. TCP offers a connection-oriented transport, while UDP offers best-effort delivery. RADIUS requires additional programmable variables such as re-transmit attempts and time-outs to compensate for best-effort transport, but it lacks the level of built-in support that a TCP transport offers.
- TACACS+ offers full packet encryption whereas RADIUS offers password-only encryption in authentication requests.
- TACACS+ separates authentication, authorization and accounting.

How TACACS+ Authentication Works

TACACS+ works much in the same way as RADIUS authentication as described on [page 86](#).

1. Remote administrator connects to the switch and provides user name and password.
2. Using Authentication/Authorization protocol, the switch sends request to authentication server.
3. Authentication server checks the request against the user ID database.
4. Using TACACS+ protocol, the authentication server instructs the switch to grant or deny administrative access.

During a session, if additional authorization checking is needed, the switch checks with a TACACS+ server to determine if the user is granted permission to use a particular command.

TACACS+ Authentication Features in Lenovo N/OS

Authentication is the action of determining the identity of a user, and is generally done when the user first attempts to log in to a device or gain access to its services. N/OS supports ASCII inbound login to the device. PAP, CHAP and ARAP login methods, TACACS+ change password requests, and one-time password authentication are not supported.

Authorization

Authorization is the action of determining a user's privileges on the device, and usually takes place after authentication.

The default mapping between TACACS+ authorization levels and N/OS management access levels is shown in [Table 9](#). The authorization levels must be defined on the TACACS+ server.

Table 9. *Default TACACS+ Authorization Levels*

N/OS User Access Level	TACACS+ level
user	0
oper	3
admin	6

Alternate mapping between TACACS+ authorization levels and N/OS management access levels is shown in [Table 10](#). Use the following command to set the alternate TACACS+ authorization levels.

```
RS 8264CS(config)# tacacs-server privilege-mapping
```

Table 10. *Alternate TACACS+ Authorization Levels*

N/OS User Access Level	TACACS+ level
user	0 - 1
oper	6 - 8
admin	14 - 15

If the remote user is successfully authenticated by the authentication server, the switch verifies the *privileges* of the remote user and authorizes the appropriate access. The administrator has an option to allow *secure backdoor* access via Telnet/SSH. Secure backdoor provides switch access when the TACACS+ servers cannot be reached. You always can access the switch via the console port, by using `notacacs` and the administrator username and password, whether secure backdoor is enabled or not.

Note: To obtain the TACACS+ backdoor password for your G8264CS, contact Technical Support.

Accounting

Accounting is the action of recording a user's activities on the device for the purposes of billing and/or security. It follows the authentication and authorization actions. If the authentication and authorization is not performed via TACACS+, there are no TACACS+ accounting messages sent out.

You can use TACACS+ to record and track software login access, configuration changes, and interactive commands.

The G8264CS supports the following TACACS+ accounting attributes:

- protocol (console/Telnet/SSH/HTTP/HTTPS)
- start_time
- stop_time
- elapsed_time

- disc_cause

Note: When using the Browser-Based Interface, the TACACS+ Accounting Stop records are sent only if the **Logout** button on the browser is clicked.

Command Authorization and Logging

When TACACS+ Command Authorization is enabled, N/OS configuration commands are sent to the TACACS+ server for authorization. Use the following command to enable TACACS+ Command Authorization:

```
RS 8264CS(config)# tacacs-server command-authorization
```

When TACACS+ Command Logging is enabled, N/OS configuration commands are logged on the TACACS+ server. Use the following command to enable TACACS+ Command Logging:

```
RS 8264CS(config)# tacacs-server command-logging
```

The following examples illustrate the format of N/OS commands sent to the TACACS+ server:

```
authorization request, cmd=shell, cmd-arg=interface ip
accounting request, cmd=shell, cmd-arg=interface ip
authorization request, cmd=shell, cmd-arg=enable
accounting request, cmd=shell, cmd-arg=enable
```

Configuring TACACS+ Authentication on the Switch

1. Configure the IPv4 addresses of the Primary and Secondary TACACS+ servers, and enable TACACS authentication. Specify the interface port (optional).

```
RS 8264CS(config)# tacacs-server primary-host 10.10.1.1
RS 8264CS(config)# tacacs-server primary-host mgt-port
RS 8264CS(config)# tacacs-server secondary-host 10.10.1.2
RS 8264CS(config)# tacacs-server secondary-host data-port
RS 8264CS(config)# tacacs-server enable
```

Note: You can use a configured loopback address as the source address so the TACACS+ server accepts requests only from the expected loopback address block. Use the following command to specify the loopback interface:

```
RS 8264CS(config)# ip tacacs source-interface loopback <1-5>
```

2. Configure the TACACS+ secret and second secret.

```
RS 8264CS(config)# tacacs-server primary-host 10.10.1.1 key
<1-32 character secret>
RS 8264CS(config)# tacacs-server secondary-host 10.10.1.2 key
<1-32 character secret>
```

3. If desired, you may change the default TCP port number used to listen to TACACS+.

The well-known port for TACACS+ is 49.

```
RS 8264CS(config)# tacacs-server port <TCP port number>
```

4. Configure the number of retry attempts, and the timeout period.

```
RS 8264CS(config)# tacacs-server retransmit 3  
RS 8264CS(config)# tacacs-server timeout 5
```

LDAP Authentication and Authorization

N/OS supports the LDAP (Lightweight Directory Access Protocol) method to authenticate and authorize remote administrators to manage the switch. LDAP is based on a client/server model. The switch acts as a client to the LDAP server. A remote user (the remote administrator) interacts only with the switch, not the back-end server and database.

LDAP authentication consists of the following components:

- A protocol with a frame format that utilizes TCP over IP
- A centralized server that stores all the user authorization information
- A client: in this case, the switch

Each entry in the LDAP server is referenced by its Distinguished Name (DN). The DN consists of the user-account name concatenated with the LDAP domain name. If the user-account name is John, the following is an example DN:

```
uid=John,ou=people,dc=domain,dc=com
```

Configuring the LDAP Server

G8264CS user groups and user accounts must reside within the same domain. On the LDAP server, configure the domain to include G8264CS user groups and user accounts, as follows:

- User Accounts:
Use the *uid* attribute to define each individual user account.
- User Groups:
Use the *members* attribute in the *groupOfNames* object class to create the user groups. The first word of the common name for each user group must be equal to the user group names defined in the G8264CS, as follows:
 - o admin
 - o oper
 - o user

Configuring LDAP Authentication on the Switch

1. Turn LDAP authentication on, then configure the IPv4 addresses of the Primary and Secondary LDAP servers. Specify the interface port (optional).

```
>> # ldap-server enable
>> # ldap-server primary-host 10.10.1.1 mgt-port
>> # ldap-server secondary-host 10.10.1.2 data-port
```

2. Configure the domain name.

```
>> # ldap-server domain <ou=people,dc=my-domain,dc=com>
```

3. You may change the default TCP port number used to listen to LDAP (optional).

The well-known port for LDAP is 389.

```
>> # ldap-server port <1-65000>
```

4. Configure the number of retry attempts for contacting the LDAP server, and the timeout period.

```
>> # ldap-server retransmit 3  
>> # ldap-server timeout 10
```

Chapter 7. 802.1X Port-Based Network Access Control

Port-Based Network Access control provides a means of authenticating and authorizing devices attached to a LAN port that has point-to-point connection characteristics. It prevents access to ports that fail authentication and authorization. This feature provides security to ports of the RackSwitch G8264CS (G8264CS) that connect to blade servers.

The following topics are discussed in this section:

- [“Extensible Authentication Protocol over LAN” on page 98](#)
- [“EAPoL Authentication Process” on page 99](#)
- [“EAPoL Port States” on page 101](#)
- [“Guest VLAN” on page 101](#)
- [“Supported RADIUS Attributes” on page 102](#)
- [“EAPoL Configuration Guidelines” on page 104](#)

Extensible Authentication Protocol over LAN

Lenovo Networking OS can provide user-level security for its ports using the IEEE 802.1X protocol, which is a more secure alternative to other methods of port-based network access control. Any device attached to an 802.1X-enabled port that fails authentication is prevented access to the network and denied services offered through that port.

The 802.1X standard describes port-based network access control using Extensible Authentication Protocol over LAN (EAPoL). EAPoL provides a means of authenticating and authorizing devices attached to a LAN port that has point-to-point connection characteristics and of preventing access to that port in cases of authentication and authorization failures.

EAPoL is a client-server protocol that has the following components:

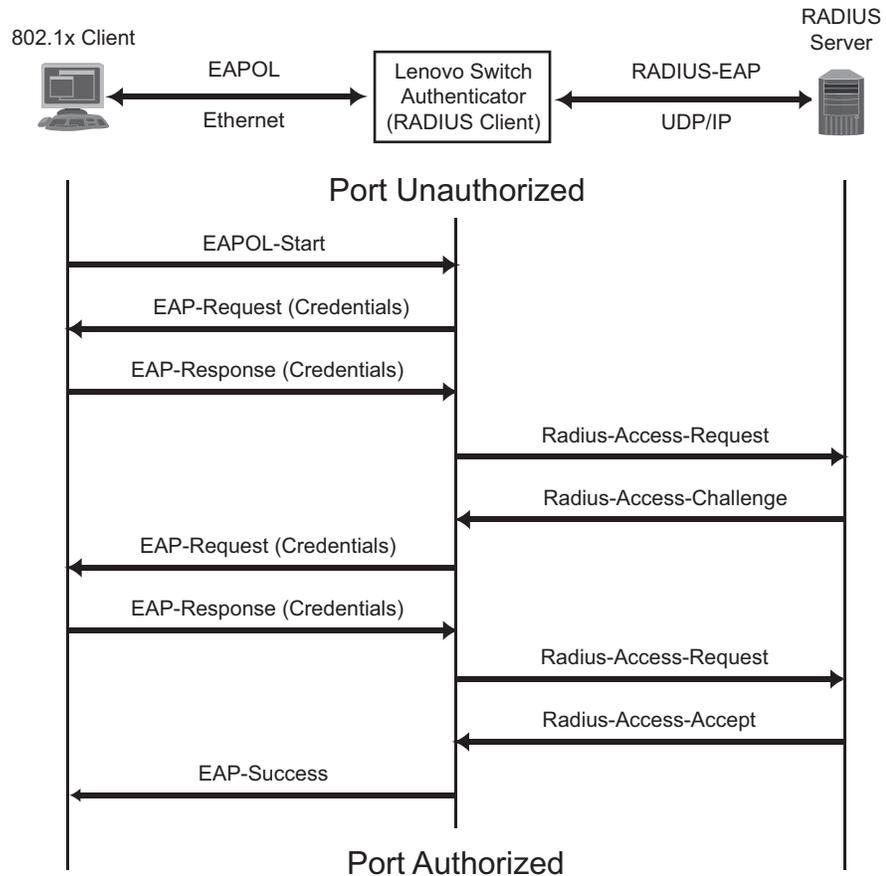

- **Supplicant or Client**
The Supplicant is a device that requests network access and provides the required credentials (user name and password) to the Authenticator and the Authentication Server.
- **Authenticator**
The Authenticator enforces authentication and controls access to the network. The Authenticator grants network access based on the information provided by the Supplicant and the response from the Authentication Server. The Authenticator acts as an intermediary between the Supplicant and the Authentication Server: requesting identity information from the client, forwarding that information to the Authentication Server for validation, relaying the server's responses to the client, and authorizing network access based on the results of the authentication exchange. The G8264CS acts as an Authenticator.
- **Authentication Server**
The Authentication Server validates the credentials provided by the Supplicant to determine if the Authenticator ought to grant access to the network. The Authentication Server may be co-located with the Authenticator. The G8264CS relies on external RADIUS servers for authentication.

Upon a successful authentication of the client by the server, the 802.1X-controlled port transitions from unauthorized to authorized state, and the client is allowed full access to services through the port. When the client sends an EAP-Logoff message to the authenticator, the port will transition from authorized to unauthorized state.

EAPoL Authentication Process

The clients and authenticators communicate using Extensible Authentication Protocol (EAP), which was originally designed to run over PPP, and for which the IEEE 802.1X Standard has defined an encapsulation method over Ethernet frames, called EAP over LAN (EAPOL). Figure 1 shows a typical message exchange initiated by the client.

Figure 1. Authenticating a Port Using EAPoL

EAPoL Message Exchange

During authentication, EAPoL messages are exchanged between the client and the G8264CS authenticator, while RADIUS-EAP messages are exchanged between the G8264CS authenticator and the RADIUS server.

Authentication is initiated by one of the following methods:

- The G8264CS authenticator sends an EAP-Request/Identity packet to the client
- The client sends an EAPoL-Start frame to the G8264CS authenticator, which responds with an EAP-Request/Identity frame.

The client confirms its identity by sending an EAP-Response/Identity frame to the G8264CS authenticator, which forwards the frame encapsulated in a RADIUS packet to the server.

The RADIUS authentication server chooses an EAP-supported authentication algorithm to verify the client's identity, and sends an EAP-Request packet to the client via the G8264CS authenticator. The client then replies to the RADIUS server with an EAP-Response containing its credentials.

Upon a successful authentication of the client by the server, the 802.1X-controlled port transitions from unauthorized to authorized state, and the client is allowed full access to services through the controlled port. When the client later sends an EAPoL-Logoff message to the G8264CS authenticator, the port transitions from authorized to unauthorized state.

If a client that does not support 802.1X connects to an 802.1X-controlled port, the G8264CS authenticator requests the client's identity when it detects a change in the operational state of the port. The client does not respond to the request, and the port remains in the unauthorized state.

Note: When an 802.1X-enabled client connects to a port that is not 802.1X-controlled, the client initiates the authentication process by sending an EAPoL-Start frame. When no response is received, the client retransmits the request for a fixed number of times. If no response is received, the client assumes the port is in authorized state, and begins sending frames, even if the port is unauthorized.

EAPoL Port States

The state of the port determines whether the client is granted access to the network, as follows:

- **Unauthorized**
While in this state the port discards all ingress and egress traffic except EAP packets.
- **Authorized**
When the client is successfully authenticated, the port transitions to the authorized state allowing all traffic to and from the client to flow normally.
- **Force Unauthorized**
You can configure this state that denies all access to the port.
- **Force Authorized**
You can configure this state that allows full access to the port.

Use the 802.1X global configuration commands (`dot1x`) to configure 802.1X authentication for all ports in the switch. Use the 802.1X port commands to configure a single port.

Guest VLAN

The guest VLAN provides limited access to unauthenticated ports. The guest VLAN can be configured using the following commands:

```
RS 8264CS(config)# dot1x guest-vlan ?
```

Client ports that have not received an EAPoL response are placed into the Guest VLAN, if one is configured on the switch. Once the port is authenticated, it is moved from the Guest VLAN to its configured VLAN.

When Guest VLAN enabled, the following considerations apply while a port is in the unauthenticated state:

- The port is placed in the guest VLAN.
- The Port VLAN ID (PVID) is changed to the Guest VLAN ID.
- Port tagging is disabled on the port.

Supported RADIUS Attributes

The 802.1X Authenticator relies on external RADIUS servers for authentication with EAP. Table 11 lists the RADIUS attributes that are supported as part of RADIUS-EAP authentication based on the guidelines specified in Annex D of the 802.1X standard and RFC 3580.

Table 11. *Support for RADIUS Attributes*

#	Attribute	Attribute Value	A-R	A-A	A-C	A-R
1	User-Name	The value of the Type-Data field from the supplicant's EAP-Response/ Identity message. If the Identity is unknown (for example, Type-Data field is zero bytes in length), this attribute will have the same value as the Calling-Station-Id.	1	0-1	0	0
4	NAS-IP-Address	IPv4 address of the authenticator used for Radius communication.	1	0	0	0
5	NAS-Port	Port number of the authenticator port to which the supplicant is attached.	1	0	0	0
24	State	Server-specific value. This is sent unmodified back to the server in an Access-Request that is in response to an Access-Challenge.	0-1	0-1	0-1	0
30	Called-Station-ID	The MAC address of the authenticator encoded as an ASCII string in canonical format, such as 000D5622E3 9F.	1	0	0	0
31	Calling-Station-ID	The MAC address of the supplicant encoded as an ASCII string in canonical format, such as 00034B436206.	1	0	0	0
64	Tunnel-Type	Only VLAN (type 13) is currently supported (for 802.1X RADIUS VLAN assignment). The attribute must be untagged (the Tag field must be 0).	0	0-1	0	0
65	Tunnel-Medium-Type	Only 802 (type 6) is currently supported (for 802.1X RADIUS VLAN assignment). The attribute must be untagged (the Tag field must be 0).	0	0-1	0	0

Table 11. Support for RADIUS Attributes (continued)

#	Attribute	Attribute Value	A-R	A-A	A-C	A-R
81	Tunnel-Private-Group-ID	VLAN ID (1-4094). When 802.1X RADIUS VLAN assignment is enabled on a port, if the RADIUS server includes the tunnel attributes defined in RFC 2868 in the Access-Accept packet, the switch will automatically place the authenticated port in the specified VLAN. Reserved VLANs (such as for management) may not be specified. The attribute must be untagged (the Tag field must be 0).	0	0-1	0	0
79	EAP-Message	Encapsulated EAP packets from the supplicant to the authentication server (Radius) and vice-versa. The authenticator relays the decoded packet to both devices.	1+	1+	1+	1+
80	Message-Authenticator	Always present whenever an EAP-Message attribute is also included. Used to integrity-protect a packet.	1	1	1	1
87	NAS-Port-ID	Name assigned to the authenticator port, e.g. Server1_Port3	1	0	0	0

Legend: RADIUS Packet Types: A-R (Access-Request), A-A (Access-Accept), A-C (Access-Challenge), A-R (Access-Reject)

RADIUS Attribute Support:

- 0 This attribute MUST NOT be present in a packet.
- 0+ Zero or more instances of this attribute MAY be present in a packet.
- 0-1 Zero or one instance of this attribute MAY be present in a packet.
- 1 Exactly one instance of this attribute MUST be present in a packet.
- 1+ One or more of these attributes MUST be present.

EAPoL Configuration Guidelines

When configuring EAPoL, consider the following guidelines:

- The 802.1X port-based authentication is currently supported only in point-to-point configurations, that is, with a single supplicant connected to an 802.1X-enabled switch port.
- When 802.1X is enabled, a port has to be in the authorized state before any other Layer 2 feature can be operationally enabled. For example, the STG state of a port is operationally disabled while the port is in the unauthorized state.
- The 802.1X supplicant capability is not supported. Therefore, none of its ports can successfully connect to an 802.1X-enabled port of another device, such as another switch, that acts as an authenticator, unless access control on the remote port is disabled or is configured in forced-authorized mode. For example, if a G8264CS is connected to another G8264CS, and if 802.1X is enabled on both switches, the two connected ports must be configured in force-authorized mode.
- Unsupported 802.1X attributes include Service-Type, Session-Timeout, and Termination-Action.
- RADIUS accounting service for 802.1X-authenticated devices or users is not currently supported.
- Configuration changes performed using SNMP and the standard 802.1X MIB will take effect immediately.

Chapter 8. Access Control Lists

Access Control Lists (ACLs) are filters that permit or deny traffic for security purposes. They can also be used with QoS to classify and segment traffic to provide different levels of service to different traffic types. Each filter defines the conditions that must match for inclusion in the filter, and also the actions that are performed when a match is made.

Lenovo Networking OS 8.2 supports the following ACLs:

- IPv4 ACLs

Up to 256 ACLs are supported for networks that use IPv4 addressing. IPv4 ACLs are configured using the following ISCLI command path:

```
RS 8264CS(config)# access-control list <IPv4 ACL number> ?
```

- IPv6 ACLs

Up to 128 ACLs are supported for networks that use IPv6 addressing. IPv6 ACLs are configured using the following ISCLI command path:

```
RS 8264CS(config)# access-control list6 <IPv6 ACL number> ?
```

- VLAN Maps (VMaps)

Up to 128 VLAN Maps are supported for attaching filters to VLANs rather than ports. See [“VLAN Maps” on page 117](#) for details.

Summary of Packet Classifiers

ACLs allow you to classify packets according to a variety of content in the packet header (such as the source address, destination address, source port number, destination port number, and others). Once classified, packet flows can be identified for more processing.

IPv4 ACLs, IPv6 ACLs, and VMaps allow you to classify packets based on the following packet attributes:

- Ethernet header options (for IPv4 ACLs and VMaps only)
 - Source MAC address
 - Destination MAC address
 - VLAN number and mask
 - Ethernet type (ARP, IP, IPv6, MPLS, RARP, etc.)
 - Ethernet Priority (the IEEE 802.1p Priority)
- IPv4 header options (for IPv4 ACLs and VMaps only)
 - Source IPv4 address and subnet mask
 - Destination IPv4 address and subnet mask
 - Type of Service value
 - IP protocol number or name as shown in [Table 12](#):

Table 12. *Well-Known Protocol Types*

Number	Protocol Name
1	icmp
2	igmp
6	tcp
17	udp
89	ospf
112	vrrp

- IPv6 header options (for IPv6 ACLs only)
 - Source IPv6 address and prefix length
 - Destination IPv6 address and prefix length
 - Next Header value
 - Flow Label value
 - Traffic Class value

- TCP/UDP header options (for all ACLs)
 - TCP/UDP application source port and mask as shown in [Table 13](#)
 - TCP/UDP application destination port as shown in [Table 13](#)

Table 13. Well-Known Application Ports

Port	TCP/UDP Application	Port	TCP/UDP Application	Port	TCP/UDP Application
20	ftp-data	79	finger	179	bgp
21	ftp	80	http	194	irc
22	ssh	109	pop2	220	imap3
23	telnet	110	pop3	389	ldap
25	smtp	111	sunrpc	443	https
37	time	119	nntp	520	rip
42	name	123	ntp	554	rtsp
43	whois	143	imap	1645/1812	Radius
53	domain	144	news	1813	Radius
69	tftp	161	snmp	1985	Accounting
70	gopher	162	snmptrap		hsrp

- TCP/UDP flag value as shown in [Table 14](#)

Table 14. Well-Known TCP flag values

Flag	Value
URG	0x0020
ACK	0x0010
PSH	0x0008
RST	0x0004
SYN	0x0002
FIN	0x0001

- Packet format (for IPv4 ACLs and VMaps only)
 - Ethernet format (eth2, SNAP, LLC)
 - Ethernet tagging format
 - IP format (IPv4, IPv6)
- Egress port packets (for all ACLs)

Summary of ACL Actions

Once classified using ACLs, the identified packet flows can be processed differently. For each ACL, an *action* can be assigned. The action determines how the switch treats packets that match the classifiers assigned to the ACL. G8264CS ACL actions include the following:

- Pass or Drop the packet
- Re-mark the packet with a new DiffServ Code Point (DSCP)
- Re-mark the 802.1p field
- Set the COS queue

Assigning Individual ACLs to a Port

Once you configure an ACL, you must assign the ACL to the appropriate ports. Each port can accept multiple ACLs, and each ACL can be applied for multiple ports. ACLs can be assigned individually.

To assign an individual ACLs to a port, use the following IP Interface Mode commands:

```
RS 8264CS(config)# interface port <port>
RS 8264CS(config-if)# access-control list <IPv4 ACL number>
RS 8264CS(config-if)# access-control list6 <IPv6 ACL number>
```

When multiple ACLs are assigned to a port, higher-priority ACLs are considered first, and their action takes precedence over lower-priority ACLs. ACL order of precedence is discussed in the next section.

ACL Order of Precedence

When multiple ACLs are assigned to a port, they are evaluated in numeric sequence, based on the ACL number. Lower-numbered ACLs take precedence over higher-numbered ACLs. For example, ACL 1 (if assigned to the port) is evaluated first and has top priority.

If multiple ACLs match the port traffic, only the action of the one with the lowest ACL number is applied. The others are ignored.

If no assigned ACL matches the port traffic, no ACL action is applied.

ACL Metering and Re-Marking

You can define a profile for the aggregate traffic flowing through the G8264CS by configuring a QoS meter (if desired) and assigning ACLs to ports.

Note: When you add ACLs to a port, make sure they are ordered correctly in terms of precedence (see [“ACL Order of Precedence” on page 109](#)).

Actions taken by an ACL are called *In-Profile* actions. You can configure additional In-Profile and Out-of-Profile actions on a port. Data traffic can be metered, and re-marked to ensure that the traffic flow provides certain levels of service in terms of bandwidth for different types of network traffic.

Metering

QoS metering provides different levels of service to data streams through user-configurable parameters. A meter is used to measure the traffic stream against a traffic profile which you create. Thus, creating meters yields In-Profile and Out-of-Profile traffic for each ACL, as follows:

- **In-Profile**If there is no meter configured or if the packet conforms to the meter, the packet is classified as In-Profile.
- **Out-of-Profile**If a meter is configured and the packet does not conform to the meter (exceeds the committed rate or maximum burst rate of the meter), the packet is classified as Out-of-Profile.

Using meters, you set a Committed Rate in Kbps . All traffic within this Committed Rate is In-Profile. Additionally, you can set a Maximum Burst Size that specifies an allowed data burst larger than the Committed Rate for a brief period. These parameters define the In-Profile traffic.

Meters keep the sorted packets within certain parameters. You can configure a meter on an ACL, and perform actions on metered traffic, such as packet re-marking.

Re-Marking

Re-marking allows for the treatment of packets to be reset based on new network specifications or desired levels of service. You can configure the ACL to re-mark a packet as follows:

- Change the DSCP value of a packet, used to specify the service level that traffic receives.

- Change the 802.1p priority of a packet.

Viewing ACL Statistics

ACL statistics display how many packets have “hit” (matched) each ACL. Use ACL statistics to check filter performance or to debug the ACL filter configuration.

You must enable statistics for each ACL that you wish to monitor:

```
RS 8264CS(config)# access-control list <ACL number> statistics
```

ACL Logging

ACLs are generally used to enhance port security. Traffic that matches the characteristics (source addresses, destination addresses, packet type, etc.) specified by the ACLs on specific ports is subject to the actions (chiefly permit or deny) defined by those ACLs. Although switch statistics show the number of times particular ACLs are matched, the ACL logging feature can provide additional insight into actual traffic patterns on the switch, providing packet details in the system log for network debugging or security purposes.

Enabling ACL Logging

By default, ACL logging is disabled. Enable or disable ACL logging on a per-ACL basis as follows:

```
RS 8264CS(config)# [no] access-control list <IPv4 ACL number> log
RS 8264CS(config)# [no] access-control list6 <IPv6 ACL number> log
```

Logged Information

When ACL logging is enabled on any particular ACL, the switch will collect information about packets that match the ACL. The information collected depends on the ACL type:

- For IP-based ACLs, information is collected regarding
 - Source IP address
 - Destination IP address
 - TCP/UDP port number
 - ACL action
 - Number of packets logged

For example:

```
Sep 27 4:20:28 DUT3 NOTICE ACL-LOG: %IP ACCESS LOG: list
ACL-IP-12-IN denied tcp 1.1.1.1 (0) -> 200.0.1.2 (0), 150
packets.
```

- For MAC-based ACLs, information is collected regarding
 - Source MAC address
 - Source IP address
 - Destination IP address
 - TCP/UDP port number
 - ACL action
 - Number of packets logged

For example:

```
Sep 27 4:25:38 DUT3 NOTICE ACL-LOG: %MAC ACCESS LOG: list
ACL-MAC-12-IN permitted tcp 1.1.1.2 (0) (12,
00:ff:d7:66:74:62) -> 200.0.1.2 (0) (00:18:73:ee:a7:c6), 32
packets.
```

Rate Limiting Behavior

Because ACL logging can be CPU-intensive, logging is rate-limited. By default, the switch will log only 10 matching packets per second. This pool is shared by all log-enabled ACLs. The global rate limit can be changed as follows:

```
RS 8264CS(config)# access-control log rate-limit <1-1000>
```

Where the limit is specified in packets per second.

Log Interval

For each log-enabled ACL, the first packet that matches the ACL initiates an immediate message in the system log. Beyond that, additional matches are subject to the log interval. By default, the switch will buffer ACL log messages for a period of 300 seconds. At the end of that interval, all messages in the buffer are written to the system log. The global interval value can be changed as follows:

```
RS 8264CS(config)# access-control log interval <5-600>
```

Where the interval rate is specified in seconds.

In any given interval, packets that have identical log information are condensed into a single message. However, the packet count shown in the ACL log message represents only the logged messages, which due to rate-limiting, may be significantly less than the number of packets actually matched by the ACL.

Also, the switch is limited to 64 different ACL log messages in any interval. Once the threshold is reached, the oldest message will be discarded in favor of the new message, and an overflow message will be added to the system log.

ACL Logging Limitations

ACL logging reserves packet queue 1 for internal use. Features that allow remapping packet queues (such as CoPP) may not behave as expected if other packet flows are reconfigured to use queue 1.

ACL Configuration Examples

ACL Example 1

Use this configuration to block traffic to a specific host. All traffic that ingresses on port 1 is denied if it is destined for the host at IP address 100.10.1.1

1. Configure an Access Control List.

```
RS 8264CS(config)# access-control list 1 ipv4 destination-ip-address
100.10.1.1
RS 8264CS(config)# access-control list 1 action deny
```

2. Add ACL 1 to port 1.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# access-control list 1
RS 8264CS(config-if)# exit
```

ACL Example 2

Use this configuration to block traffic from a network destined for a specific host address. All traffic that ingresses in port 2 with source IP from class 100.10.1.0/24 and destination IP 200.20.2.2 is denied.

1. Configure an Access Control List.

```
RS 8264CS(config)# access-control list 2 ipv4 source-ip-address
100.10.1.0 255.255.255.0
RS 8264CS(config)# access-control list 2 ipv4 destination-ip-address
200.20.2.2 255.255.255.255
RS 8264CS(config)# access-control list 2 action deny
```

2. Add ACL 2 to port 2.

```
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# access-control list 2
RS 8264CS(config-if)# exit
```

ACL Example 3

Use this configuration to block traffic from a specific IPv6 source address. All traffic that ingresses in port 2 with source IP from class 2001:0:0:5:0:0:0:2/128 is denied.

1. Configure an Access Control List.

```
RS 8264CS(config)# access-control list6 3 ipv6 source-address  
2001:0:0:5:0:0:0:2 128  
RS 8264CS(config)# access-control list6 3 action deny
```

2. Add ACL 2 to port 2.

```
RS 8264CS(config)# interface port 2  
RS 8264CS(config-if)# access-control list6 3  
RS 8264CS(config-if)# exit
```

ACL Example 4

Use this configuration to deny all ARP packets that ingress a port.

1. Configure an Access Control List.

```
RS 8264CS(config)# access-control list 2 ethernet ethernet-type arp  
RS 8264CS(config)# access-control list 2 action deny
```

2. Add ACL 2 to port EXT2.

```
RS 8264CS(config)# interface port 2  
RS 8264CS(config-if)# access-control list 2  
RS 8264CS(config-if)# exit
```

ACL Example 5

Use the following configuration to permit access to hosts with destination MAC address that matches 11:05:00:10:00:00 FF:F5:FF:FF:FF:FF and deny access to all other hosts.

1. Configure Access Control Lists.

```
RS 8264CS(config)# access-control list 30 ethernet  
destination-mac-address 11:05:00:10:00:00 FF:F5:FF:FF:FF:FF  
RS 8264CS(config)# access-control list 30 action permit  
RS 8264CS(config)# access-control list 100 ethernet  
destination-mac-address 00:00:00:00:00:00 00:00:00:00:00:00  
RS 8264CS(config)# access-control list 100 action deny
```

2. Add ACLs to a port.

```
RS 8264CS(config)# interface port 2  
RS 8264CS(config-if)# access-control list 30  
RS 8264CS(config-if)# access-control list 100  
RS 8264CS(config-if)# exit
```

ACL Example 6

This configuration blocks traffic from a network that is destined for a specific egress port. All traffic that ingresses port 1 from the network 100.10.1.0/24 and is destined for port 3 is denied.

1. Configure an Access Control List.

```
RS 8264CS(config)# access-control list 4 ipv4 source-ip-address  
100.10.1.0 255.255.255.0  
RS 8264CS(config)# access-control list 4 egress-port 3  
RS 8264CS(config)# access-control list 4 action deny
```

2. Add ACL 4 to port 1.

```
RS 8264CS(config)# interface port 1  
RS 8264CS(config-if)# access-control list 4  
RS 8264CS(config-if)# exit
```

VLAN Maps

A VLAN map (VMap) is an ACL that can be assigned to a VLAN or VM group rather than to a switch port as with IPv4 ACLs. This is particularly useful in a virtualized environment where traffic filtering and metering policies must follow virtual machines (VMs) as they migrate between hypervisors.

Note: VLAN maps for VM groups are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

The G8264CS supports up to 128 VMaps.

Individual VMap filters are configured in the same fashion as IPv4 ACLs, except that VLANs cannot be specified as a filtering criteria (unnecessary, since the VMap are assigned to a specific VLAN or associated with a VM group VLAN).

VMaps are configured using the following ISCLI configuration command path:

```
RS 8264CS(config)# access-control vmap <VMap ID> ?
  action          Set filter action
  egress-port     Set to filter for packets egressing this port
  ethernet        Ethernet header options
  ipv4            IP version 4 header options
  meter           ACL metering configuration
  mirror          Mirror options
  packet-format   Set to filter specific packet format types
  re-mark         ACL re-mark configuration
  statistics      Enable access control list statistics
  tcp-udp         TCP and UDP filtering options
```

Once a VMap filter is created, it can be assigned or removed using the following configuration commands:

- For regular VLAN, use config-vlan mode:

```
RS 8264CS(config)# vlan <VLAN ID>
RS 8264CS(config-vlan)# [no] vmap <VMap ID> [serverports |
non-serverports]
```

- For a VM group (see [“VM Group Types” on page 228](#)), use the global configuration mode:

```
RS 8264CS(config)# [no] virt vmgroup <ID> vmap <VMap ID>
[serverports | non-serverports]
```

Note: Each VMap can be assigned to only one VLAN or VM group. However, each VLAN or VM group may have multiple VMaps assigned to it.

When the optional `serverports` or `non-serverports` parameter is specified, the action to add or remove the VMap is applied for either the switch server ports (`serverports`) or uplink ports (`non-serverports`). If omitted, the operation will be applied to all ports in the associated VLAN or VM group.

VMap Example

In this example, EtherType 2 traffic from VLAN 3 server ports is mirrored to a network monitor on port 4.

```
RS 8264CS(config)# access-control vmap 21 packet-format ethernet
ethernet-type2
RS 8264CS(config)# access-control vmap 21 mirror port 4
RS 8264CS(config)# access-control vmap 21 action permit
RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# vmap 21 serverports
```

Using Storm Control Filters

Excessive transmission of broadcast or multicast traffic can result in a network storm. A network storm can overwhelm your network with constant broadcast or multicast traffic, and degrade network performance. Common symptoms of a network storm are denial-of-service (DoS) attacks, slow network response times, and network operations timing out.

The G8264CS provides filters that can limit the number of the following packet types transmitted by switch ports:

- Broadcast packets
- Multicast packets
- Unknown unicast packets (destination lookup failure)

Unicast packets whose destination MAC address is not in the Forwarding Database are *unknown unicasts*. When an unknown unicast is encountered, the switch handles it like a broadcast packet and floods it to all other ports in the VLAN (broadcast domain). A high rate of unknown unicast traffic can have the same negative effects as a broadcast storm.

Configuring Storm Control

Configure broadcast filters on each port that requires broadcast storm control. Set a threshold that defines the total number of broadcast packets transmitted (0-2097151), in packets per second. When the threshold is reached, no more packets of the specified type are transmitted.

To filter broadcast packets on a port, use the following commands:

```
RS 8264CS(config)# interface port 1  
RS 8264CS(config-if)# storm-control broadcast level rate <packets per second>
```

To filter multicast packets on a port, use the following commands:

```
RS 8264CS(config-if)# storm-control multicast level rate <packets per second>
```

To filter unknown unicast packets on a port, use the following commands:

```
RS 8264CS(config-if)# storm-control unicast level rate <packets per second>  
RS 8264CS(config-if)# exit
```

Part 3: Switch Basics

This section discusses basic switching functions:

- VLANs
- Port Trunking
- Spanning Tree Protocols (Spanning Tree Groups, Rapid Spanning Tree Protocol, and Multiple Spanning Tree Protocol)
- Virtual Link Aggregation Groups
- Quality of Service

Chapter 9. VLANs

This chapter describes network design and topology considerations for using Virtual Local Area Networks (VLANs). VLANs commonly are used to split up groups of network users into manageable broadcast domains, to create logical segmentation of workgroups, and to enforce security policies among logical segments. The following topics are discussed in this chapter:

- [“VLANs and Port VLAN ID Numbers” on page 124](#)
- [“VLAN Tagging/Trunk Mode” on page 126](#)
- [“VLAN Topologies and Design Considerations” on page 130](#)

This section discusses how you can connect users and segments to a host that supports many logical segments or subnets by using the flexibility of the multiple VLAN system.

- [“Protocol-Based VLANs” on page 134](#)
- [“Private VLANs” on page 137](#)

Note: VLANs can be configured from the Command Line Interface (see “VLAN Configuration” as well as “Port Configuration” in the *Command Reference*).

VLANs Overview

Setting up virtual LANs (VLANs) is a way to segment networks to increase network flexibility without changing the physical network topology. With network segmentation, each switch port connects to a segment that is a single broadcast domain. When a switch port is configured to be a member of a VLAN, it is added to a group of ports (workgroup) that belong to one broadcast domain.

Ports are grouped into broadcast domains by assigning them to the same VLAN. Frames received in one VLAN can only be forwarded within that VLAN, and multicast, broadcast, and unknown unicast frames are flooded only to ports in the same VLAN.

The RackSwitch G8264CS (G8264CS) supports jumbo frames with a Maximum Transmission Unit (MTU) of 9,216 bytes. Within each frame, 18 bytes are reserved for the Ethernet header and CRC trailer. The remaining space in the frame (up to 9,198 bytes) comprise the packet, which includes the payload of up to 9,000 bytes and any additional overhead, such as 802.1q or VLAN tags. Jumbo frame support is automatic: it is enabled by default, requires no manual configuration, and cannot be manually disabled.

VLANs and Port VLAN ID Numbers

VLAN Numbers

The G8264CS supports up to 4095 VLANs per switch. Each can be identified with any number between 1 and 4094. VLAN 1 is the default VLAN for the data ports. VLAN 4095 is used by the management network, which includes the management port.

Use the following command to view VLAN information:

```
RS 8264CS# show vlan
```

VLAN	Name	Status	Ports
1	Default VLAN	ena	1-64
2	VLAN 2	dis	empty
4095	Mgmt VLAN	ena	MGMT

PVID/Native VLAN Numbers

Each port in the switch has a configurable default VLAN number, known as its *PVID*. By default, the PVID for all non-management ports is set to 1, which correlates to the default VLAN ID. The PVID for each port can be configured to any VLAN number between 1 and 4094.

Use the following command to view PVIDs:

```
RS 8264CS# show interface information
(or)
RS 8264CS# show interface trunk
```

Alias	Port	Tag	RMON	Ln	Fld	PVID	DESCRIPTION	VLAN(s)
		Trk				NVLAN		
1	1	y	d	e	e	10	10-15	
2	2	y	d	e	e	10	10-15	
3	3	y	d	e	e	10	10-15	
4	4	y	d	e	e	10	10-15	
5	5	y	d	e	e	10	10-15	
6	6	y	d	e	e	10	10-15	
7	7	y	d	e	e	10	10-15	
.
60	60	n	d	e	e	1	1	
61	61	n	d	e	e	1	1	
62	62	n	d	e	e	1	1	
63	63	n	d	e	e	1	1	
64	64	y	d	e	e	10#	IXIA5/5	10-15
MGT	65	n	d	e	e	4095		4095

* = PVID/Native-VLAN is tagged.
= PVID is ingress tagged.
Trk = Trunk mode
NVLAN = Native-VLAN

Use the following command to set the port PVID/Native VLAN:

```
Access Mode Port
RS 8264CS(config)# interface port <port number>
RS 8264CS(config-if)# switchport access vlan <VLAN ID>

For Trunk Mode Port
RS 8264CS(config)# interface port <port number>
RS 8264CS(config-if)# switchport trunk native vlan <VLAN ID>
```

Each port on the switch can belong to one or more VLANs, and each VLAN can have any number of switch ports in its membership. Any port that belongs to multiple VLANs, however, must have VLAN *tagging*/trunk mode enabled (see [“VLAN Tagging/Trunk Mode” on page 126](#)).

VLAN Tagging/Trunk Mode

Lenovo Networking OS software supports 802.1Q VLAN *tagging*, providing standards-based VLAN support for Ethernet systems.

Tagging places the VLAN identifier in the frame header of a packet, allowing each port to belong to multiple VLANs. When you add a port to multiple VLANs, you also must enable tagging on that port.

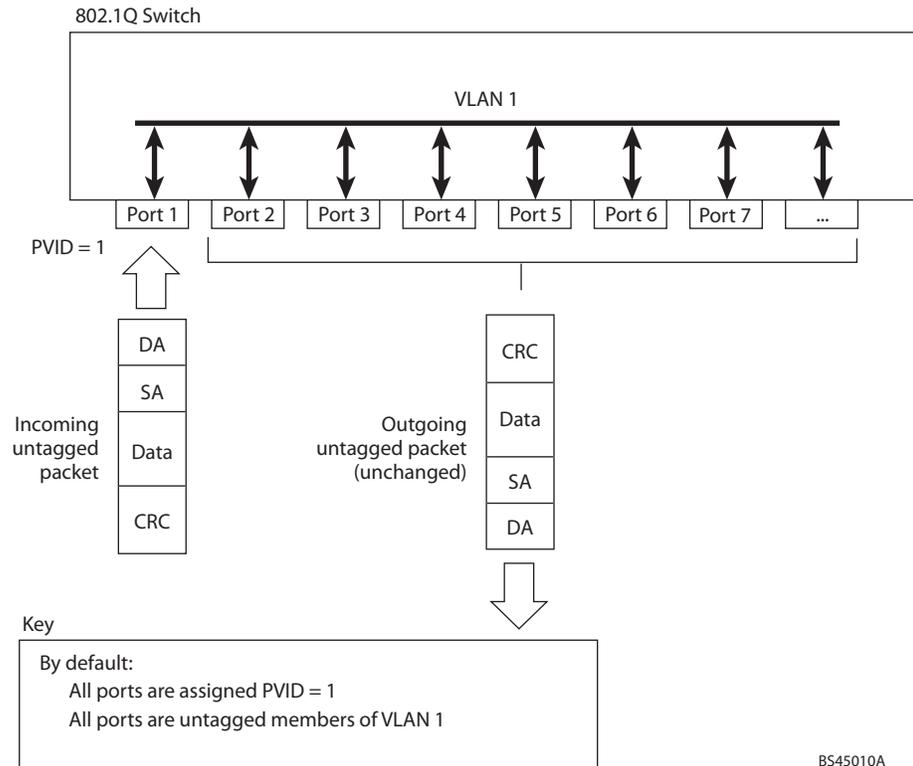

Since tagging fundamentally changes the format of frames transmitted on a tagged port, you must carefully plan network designs to prevent tagged frames from being transmitted to devices that do not support 802.1Q VLAN tags, or devices where tagging is not enabled.

Important terms used with the 802.1Q tagging feature are:

- VLAN identifier (VID)—the 12-bit portion of the VLAN tag in the frame header that identifies an explicit VLAN.
- Port VLAN identifier (PVID)—a classification mechanism that associates a port with a specific VLAN. For example, a port with a PVID of 3 (PVID =3) assigns all untagged frames received on this port to VLAN 3. Any untagged frames received by the switch are classified with the PVID of the receiving port.
- Tagged frame—a frame that carries VLAN tagging information in the header. This VLAN tagging information is a 32-bit field (VLAN tag) in the frame header that identifies the frame as belonging to a specific VLAN. Untagged frames are marked (tagged) with this classification as they leave the switch through a port that is configured as a tagged port.
- Untagged frame— a frame that does not carry any VLAN tagging information in the frame header.
- Untagged member—a port that has been configured as an untagged member of a specific VLAN. When an untagged frame exits the switch through an untagged member port, the frame header remains unchanged. When a tagged frame exits the switch through an untagged member port, the tag is stripped and the tagged frame is changed to an untagged frame.
- Tagged member—a port that has been configured as a tagged member of a specific VLAN. When an untagged frame exits the switch through a tagged member port, the frame header is modified to include the 32-bit tag associated with the PVID. When a tagged frame exits the switch through a tagged member port, the frame header remains unchanged (original VID remains).

Note: If a 802.1Q tagged frame is received by a port that has VLAN-tagging disabled and the port VLAN ID (PVID) is different than the VLAN ID of the packet, then the frame is dropped at the ingress port.

Figure 2. Default VLAN settings

Note: The port numbers specified in these illustrations may not directly correspond to the physical port configuration of your switch model.

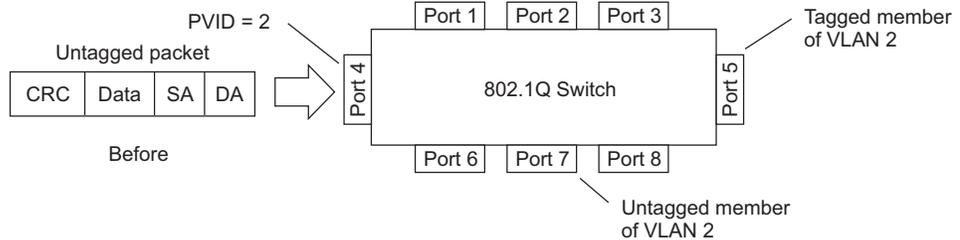

When a VLAN is configured, ports are added as members of the VLAN, and the ports are defined as either *tagged* or *untagged* (see [Figure 3](#) through [Figure 6](#)).

The default configuration settings for the G8264CS has all ports set as untagged members of VLAN 1 with all ports configured as PVID = 1. In the default configuration example shown in [Figure 2](#), all incoming packets are assigned to VLAN 1 by the default port VLAN identifier (PVID = 1).

[Figure 3](#) through [Figure 6](#) illustrate generic examples of VLAN tagging. In [Figure 3](#), untagged incoming packets are assigned directly to VLAN 2 (PVID = 2). Port 5 is configured as a *tagged* member of VLAN 2, and port 7 is configured as an *untagged* member of VLAN 2.

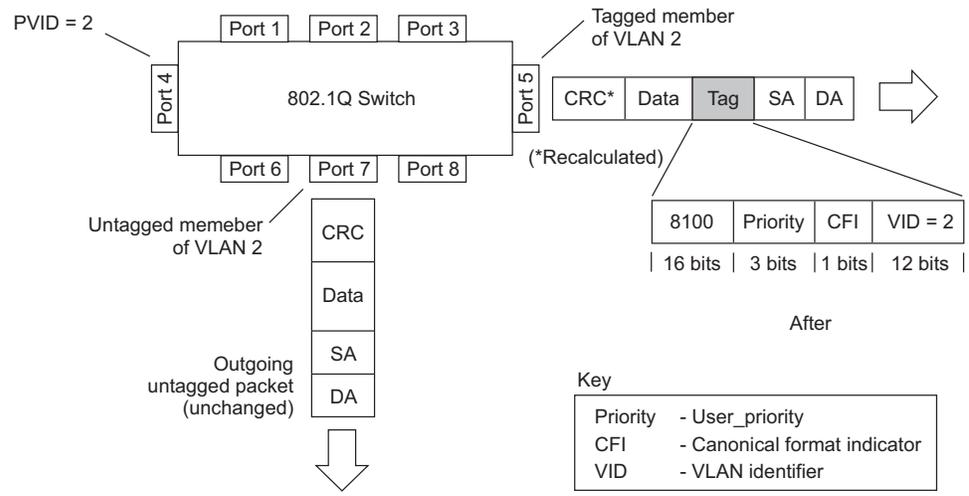

Note: The port assignments in the following figures are not meant to match the G8264CS.

Figure 3. Port-based VLAN assignment

As shown in [Figure 4](#), the untagged packet is marked (tagged) as it leaves the switch through port 5, which is configured as a tagged member of VLAN 2. The untagged packet remains unchanged as it leaves the switch through port 7, which is configured as an untagged member of VLAN 2.

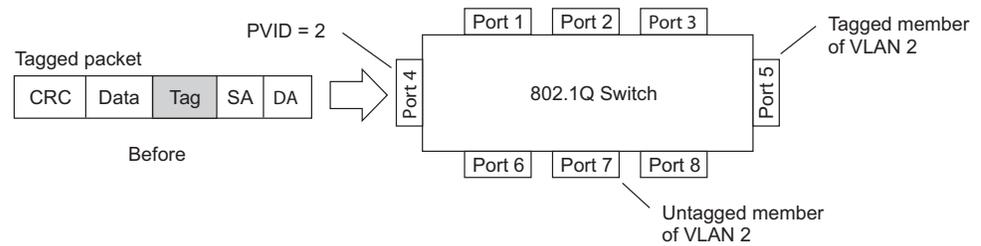

Figure 4. 802.1Q tagging (after port-based VLAN assignment)

BS45012A

In [Figure 5](#), tagged incoming packets are assigned directly to VLAN 2 because of the tag assignment in the packet. Port 5 is configured as a *tagged* member of VLAN 2, and port 7 is configured as an *untagged* member of VLAN 2.

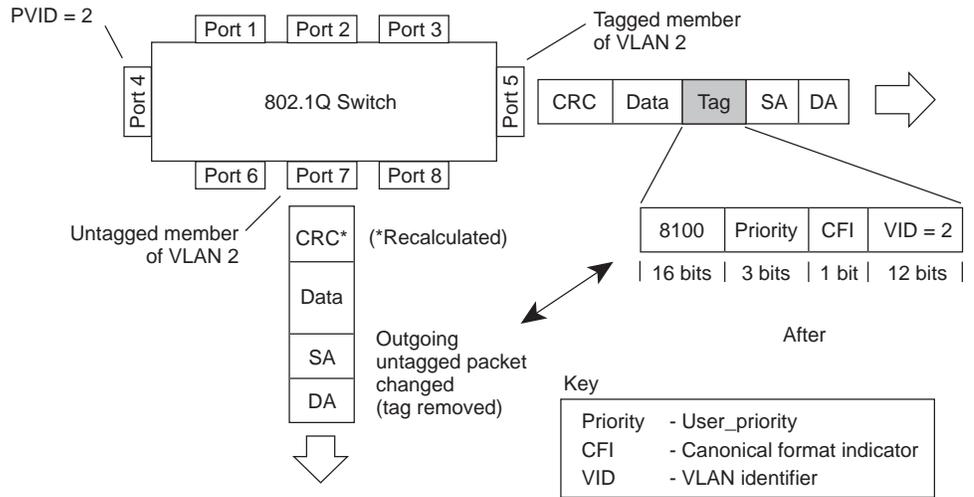

Figure 5. 802.1Q tag assignment

BS45013A

As shown in [Figure 6](#), the tagged packet remains unchanged as it leaves the switch through port 5, which is configured as a tagged member of VLAN 2. However, the tagged packet is stripped (untagged) as it leaves the switch through port 7, which is configured as an untagged member of VLAN 2.

Figure 6. 802.1Q tagging (after 802.1Q tag assignment)

BS45014A

VLAN Topologies and Design Considerations

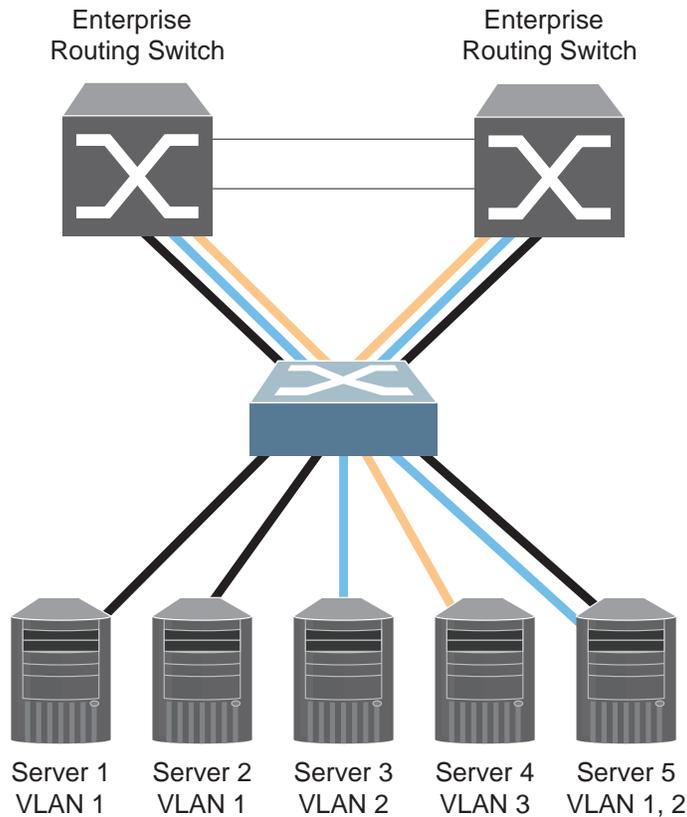

Note the following when working with VLAN topologies:

- By default, the G8264CS software is configured so that tagging/trunk mode is disabled on all ports.
- By default, the G8264CS software is configured so that all data ports are members of VLAN 1.
- By default, the Lenovo N/OS software is configured so that the management port is a member of VLAN 4095 (the management VLAN).
- STG 128 is reserved for switch management.
- When using Spanning Tree, STG 2-128 may contain only one VLAN unless Multiple Spanning-Tree Protocol (MSTP) mode is used. With MSTP mode, STG 1 to 32 can include multiple VLANs.
- All ports involved in both trunking and port mirroring must have the same VLAN configuration. If a port is on a trunk with a mirroring port, the VLAN configuration cannot be changed. For more information trunk groups, see [“Ports and Trunking” on page 141](#) and [“Port Mirroring” on page 521](#).

Multiple VLANs with Tagging/Trunk Mode Adapters

Figure 7 illustrates a network topology described in [Note: on page 132](#) and the configuration example on [page 133](#).

Figure 7. Multiple VLANs with VLAN-Tagged Gigabit Adapters

The features of this VLAN are described in the following table.

Table 15. *Multiple VLANs Example*

Component	Description
G8264CS switch	This switch is configured with three VLANs that represent three different IP subnets. Five ports are connected downstream to servers. Two ports are connected upstream to routing switches. Uplink ports are members of all three VLANs, with VLAN tagging/trunk mode enabled.
Server 1	This server is a member of VLAN 1 and has presence in only one IP subnet. The associated switch port is only a member of VLAN 1, so tagging/trunk mode is disabled.
Server 2	This server is a member of VLAN 1 and has presence in only one IP subnet. The associated switch port is only a member of VLAN 1, so tagging/trunk mode is disabled.

Table 15. Multiple VLANs Example (continued)

Component	Description
Server 3	This server belongs to VLAN 2, and it is logically in the same IP subnet as Server 5. The associated switch port has tagging/trunk mode disabled.
Server 4	A member of VLAN 3, this server can communicate only with other servers via a router. The associated switch port has tagging/trunk mode disabled.
Server 5	A member of VLAN 1 and VLAN 2, this server can communicate only with Server 1, Server 2, and Server 3. The associated switch port has tagging/trunk mode enabled.
Enterprise Routing switches	These switches must have all three VLANs (VLAN 1, 2, 3) configured. They can communicate with Server 1, Server 2, and Server 5 via VLAN 1. They can communicate with Server 3 and Server 5 via VLAN 2. They can communicate with Server 4 via VLAN 3. Tagging/trunk mode on switch ports is enabled.

Note: VLAN tagging/trunk mode is required only on ports that are connected to other switches or on ports that connect to tag-capable end-stations, such as servers with VLAN-tagging/trunk mode adapters.

To configure a specific VLAN on a trunk port, the following conditions must be met:

- The port must be in trunk mode.
- The VLAN must be in the trunk's allowed VLAN range. By default, the range includes all VLANs for Ethernet ports or VLAN 1 for Fibre Channel ports.
- The VLAN must be un-reserved.
- The VLAN must be created.

The order in which the conditions above are met is not relevant. However, all conditions must be met collectively. When the final condition is met, the VLAN is enabled on the port. When the first condition is broken, the VLAN is disabled.

VLAN Configuration Example

Use the following procedure to configure the example network shown in [Figure 7 on page 131](#).

1. Enable VLAN tagging/trunk mode on server ports that support multiple VLANs.

```
RS 8264CS(config)# interface port 5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

2. Enable tagging/trunk mode on uplink ports that support multiple VLANs.

```
RS 8264CS(config)# interface port 19
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 20
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

3. Configure server ports that belong to a single VLAN.

```
RS 8264CS(config)# interface port 4
RS 8264CS(config-if)# switchport mode access
RS 8264CS(config-if)# switchport access vlan 3
RS 8264CS(config-if)# exit
```

By default, all ports are members of VLAN 1, so configure only those ports that belong to other VLANs.

Protocol-Based VLANs

Protocol-based VLANs (PVLANS) allow you to segment network traffic according to the network protocols in use. Traffic for supported network protocols can be confined to a particular port-based VLAN. You can give different priority levels to traffic generated by different network protocols.

With PVLAN, the switch classifies incoming packets by Ethernet protocol of the packets, not by the configuration of the ingress port. When an untagged or priority-tagged frame arrives at an ingress port, the protocol information carried in the frame is used to determine a VLAN to which the frame belongs. If a frame's protocol is not recognized as a pre-defined PVLAN type, the ingress port's PVID is assigned to the frame. When a tagged frame arrives, the VLAN ID in the frame's tag is used.

Each VLAN can contain up to eight different PVLANS. You can configure separate PVLANS on different VLANs, with each PVLAN segmenting traffic for the same protocol type. For example, you can configure PVLAN 1 on VLAN 2 to segment IPv4 traffic, and PVLAN 8 on VLAN 100 to segment IPv4 traffic.

To define a PVLAN on a VLAN, configure a PVLAN number (1-8) and specify the frame type and the Ethernet type of the PVLAN protocol. You must assign at least one port to the PVLAN before it can function. Define the PVLAN frame type and Ethernet type as follows:

- Frame type—consists of one of the following values:
 - Ether2 (Ethernet II)
 - SNAP (Subnetwork Access Protocol)
 - LLC (Logical Link Control)
- Ethernet type—consists of a 4-digit (16 bit) hex value that defines the Ethernet type. You can use common Ethernet protocol values, or define your own values. Following are examples of common Ethernet protocol values:
 - IPv4 = 0800
 - IPv6 = 86dd
 - ARP = 0806

Port-Based vs. Protocol-Based VLANs

Each VLAN supports both port-based and protocol-based association, as follows:

- The default VLAN configuration is port-based. All data ports are members of VLAN 1, with no PVLAN association.
- When you add ports to a PVLAN, the ports become members of both the port-based VLAN and the PVLAN. For example, if you add port 1 to PVLAN 1 on VLAN 2, the port also becomes a member of VLAN 2.
- When you delete a PVLAN, its member ports remain members of the port-based VLAN. For example, if you delete PVLAN 1 from VLAN 2, port 1 remains a member of VLAN 2.
- When you delete a port from a VLAN, the port is deleted from all corresponding PVLANS.

PVLAN Priority Levels

You can assign each PVLAN a priority value of 0-7, used for Quality of Service (QoS). PVLAN priority takes precedence over a port's configured priority level. If no priority level is configured for the PVLAN (priority = 0), each port's priority is used (if configured).

All member ports of a PVLAN have the same PVLAN priority level.

PVLAN Tagging/Trunk Mode

When PVLAN tagging is enabled, the switch tags frames that match the PVLAN protocol. For more information about tagging, see [“VLAN Tagging/Trunk Mode” on page 126](#).

Untagged ports must have PVLAN tagging disabled. Tagged ports can have PVLAN tagging either enabled or disabled.

PVLAN tagging has higher precedence than port-based tagging. If a port is tagging/trunk mode enabled, and the port is a member of a PVLAN, the PVLAN tags egress frames that match the PVLAN protocol.

Use the tag list command (`protocol-vlan <x> tag-pvlan`) to define the complete list of tag-enabled ports in the PVLAN. Note that all ports not included in the PVLAN tag list will have PVLAN tagging disabled.

PVLAN Configuration Guidelines

Consider the following guidelines when you configure protocol-based VLANs:

- Each port can support up to 16 VLAN protocols.
- The G8264CS can support up to 16 protocols simultaneously.
- Each PVLAN must have at least one port assigned before it can be activated.
- The same port within a port-based VLAN can belong to multiple PVLANS.
- An untagged port can be a member of multiple PVLANS.
- A port cannot be a member of different VLANs with the same protocol association.

Configuring PVLAN

Follow this procedure to configure a Protocol-based VLAN (PVLAN).

1. Configure VLAN tagging/trunk mode for ports.

```
RS 8264CS(config)# interface port 1, 2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

2. Create a VLAN and define the protocol type(s) supported by the VLAN.

```
RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# no shutdown
RS 8264CS(config-vlan)# protocol-vlan 1 frame-type ether2 0800
```

3. Configure the priority value for the protocol.

```
RS 8264CS(config-vlan)# protocol-vlan 1 priority 2
```

4. Add member ports for this PVLAN.

```
RS 8264CS(config-vlan)# protocol-vlan 1 member 1, 2
```

Note: If VLAN tagging is turned on and the port being added to the VLAN has a different default VLAN (PVID/Native VLAN), you will be asked to confirm changing the PVID to the current VLAN.

5. Enable the PVLAN.

```
RS 8264CS(config-vlan)# protocol-vlan 1 enable
RS 8264CS(config-vlan)# exit
```

6. Verify PVLAN operation.

Private VLANs

Private VLANs provide Layer 2 isolation between the ports within the same broadcast domain. Private VLANs can control traffic within a VLAN domain, and provide port-based security for host servers.

Lenovo N/OS supports Private VLAN configuration as described in RFC 5517.

Use Private VLANs to partition a VLAN domain into sub-domains. Each sub-domain is comprised of one primary VLAN and one or more secondary VLANs, as follows:

- Primary VLAN—carries unidirectional traffic downstream from promiscuous ports. Each Private VLAN configuration has only one primary VLAN. All ports in the Private VLAN are members of the primary VLAN.
- Secondary VLAN—Secondary VLANs are internal to a private VLAN domain, and are defined as follows:
 - Isolated VLAN—carries unidirectional traffic upstream from the host servers toward ports in the primary VLAN. Each Private VLAN configuration can contain only one isolated VLAN.
 - Community VLAN—carries upstream traffic from ports in the community VLAN to other ports in the same community, and to ports in the primary VLAN. Each Private VLAN configuration can contain multiple community VLANs.

After you define the primary VLAN and one or more secondary VLANs, you map the secondary VLAN(s) to the primary VLAN.

Private VLAN Ports

Private VLAN ports are defined as follows:

- Promiscuous—A promiscuous port is a port that belongs to the primary VLAN. The promiscuous port can communicate with all the interfaces, including ports in the secondary VLANs (Isolated VLAN and Community VLANs).
- Isolated—An isolated port is a host port that belongs to an isolated VLAN. Each isolated port has complete layer 2 separation from other ports within the same private VLAN (including other isolated ports), except for the promiscuous ports.
 - Traffic sent to an isolated port is blocked by the Private VLAN, except the traffic from promiscuous ports.
 - Traffic received from an isolated port is forwarded only to promiscuous ports.
- Community—A community port is a host port that belongs to a community VLAN. Community ports can communicate with other ports in the same community VLAN, and with promiscuous ports. These interfaces are isolated at layer 2 from all other interfaces in other communities and from isolated ports within the Private VLAN.

Configuration Guidelines

The following guidelines apply when configuring Private VLANs:

- The default VLAN 1 cannot be a Private VLAN.
- The management VLAN 4095 cannot be a Private VLAN. Management ports cannot be members of Private VLANs.
- IGMP Snooping is not supported on Private VLANs.
- All VLANs that comprise the Private VLAN must belong to the same Spanning Tree Group.

Configuration Example

Follow this procedure to configure a Private VLAN.

1. Select a VLAN and define the Private VLAN type as primary.

```
RS 8264CS(config)# vlan 700
RS 8264CS(config-vlan)# private-vlan primary
RS 8264CS(config-vlan)# exit
```

2. Configure a promiscuous port for VLAN 700.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport mode private-vlan
RS 8264CS(config-if)# switchport private-vlan mapping 700
RS 8264CS(config-if)# exit
```

3. Configure two secondary VLANs: isolated VLAN and community VLAN.

```
RS 8264CS(config)# vlan 701
RS 8264CS(config-vlan)# private-vlan isolated
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# vlan 702
RS 8264CS(config-vlan)# private-vlan community
RS 8264CS(config-vlan)# exit
```

4. Map secondary VLANs to primary VLAN.

```
RS 8264CS(config)# vlan 700-702
RS 8264CS(config-vlan)# stg 1
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# vlan 700
RS 8264CS(config-vlan)# private-vlan association 701,702
RS 8264CS(config-vlan)# exit
```

5. Configure host ports for secondary VLANs.

```
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport mode private-vlan
RS 8264CS(config-if)# switchport private-vlan host-association 700 701
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 3
RS 8264CS(config-if)# switchport mode private-vlan
RS 8264CS(config-if)# switchport private-vlan host-association 700 702
RS 8264CS(config-if)# exit
```

6. Verify the configuration.

```
RS 8264CS(config)# show vlan private-vlan
```

Primary	Secondary	Type	Ports	vPorts
700	701	isolated	1 2	empty
700	702	community	1 3	empty

Chapter 10. Ports and Trunking

Trunk groups can provide super-bandwidth, multi-link connections between the RackSwitch G8264CS (G8264CS) and other trunk-capable devices. A trunk group is a group of ports that act together, combining their bandwidth to create a single, larger virtual link. This chapter provides configuration background and examples for trunking multiple ports together:

- [“Configuring QSFP+ Ports” on page 142](#)
- [“Trunking Overview” on page 144”](#)
- [“Configuring a Static Port Trunk” on page 146](#)
- [“Configurable Trunk Hash Algorithm” on page 152](#)
- [“Link Aggregation Control Protocol” on page 148](#)

Configuring QSFP+ Ports

QSFP+ ports support both 10GbE and 40GbE, as shown in [Table 16](#).

Table 16. *QSFP+ Port Numbering*

Physical Port Number	40GbE mode	10GbE mode
Port 1	Port 1	Ports 1-4
Port 5	Port 5	Ports 5-8
Port 9	Port 9	Ports 9-12
Port 13	Port 13	Ports 13-16

Use the following procedure to change the QSFP+ port mode.

1. Display the current port mode for the QSFP+ ports.

```
# show boot qsf-p-port-modes

QSFP ports booted configuration:
Port 1, 2, 3, 4 - 10G Mode
Port 5, 6, 7, 8 - 10G Mode
Port 9, 10, 11, 12 - 10G Mode
Port 13, 14, 15, 16 - 10G Mode

QSFP ports saved configuration:
Port 1, 2, 3, 4 - 10G Mode
Port 5, 6, 7, 8 - 10G Mode
Port 9, 10, 11, 12 - 10G Mode
Port 13, 14, 15, 16 - 10G Mode
```

2. Change the port mode to 40GbE. Select the physical port number.

```
RS 8264CS(config)# boot qsf-p-40Gports 5
```

3. Verify the change.

```
# show boot qsf-p-port-modes

QSFP ports booted configuration:
Port 1, 2, 3, 4 - 10G Mode
Port 5, 6, 7, 8 - 10G Mode
Port 9, 10, 11, 12 - 10G Mode
Port 13, 14, 15, 16 - 10G Mode

QSFP ports saved configuration:
Port 1, 2, 3, 4 - 10G Mode
Port 5 - 40G Mode
Port 9, 10, 11, 12 - 10G Mode
Port 13, 14, 15, 16 - 10G Mode
```

4. Reset the switch.

```
RS 8264CS(config)# reload
```

Use the 'no' form of the command to reset a port to 10GbE mode.

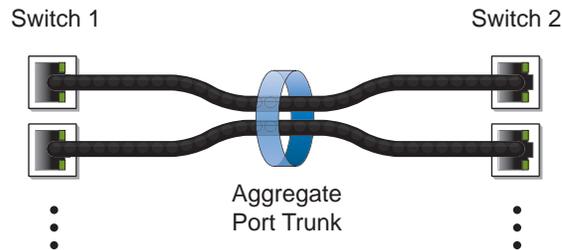

```
RS 8264CS(config)# no boot qsfp-40Gports <port number or a range of ports>
```

Trunking Overview

When using port trunk groups between two switches, as shown in [Figure 8](#), you can create a virtual link between the switches, operating with combined throughput levels that depends on how many physical ports are included.

Each G8264CS supports up to 64 trunk groups. Two trunk types are available: static trunk groups (portchannel), and dynamic LACP trunk groups. Each type can contain up to 16 member ports, depending on the port type and availability.

Figure 8. Port Trunk Group

Trunk groups are also useful for connecting a G8264CS to third-party devices that support link aggregation, such as Cisco routers and switches with EtherChannel technology (*not* ISL trunking technology) and Sun's Quad Fast Ethernet Adapter. Trunk Group technology is compatible with these devices when they are configured manually.

Trunk traffic is statistically distributed among the ports in a trunk group, based on a variety of configurable options.

Also, since each trunk group is comprised of multiple physical links, the trunk group is inherently fault tolerant. As long as one connection between the switches is available, the trunk remains active and statistical load balancing is maintained whenever a port in a trunk group is lost or returned to service.

Static Trunks

Static Trunk Requirements

When you create and enable a static trunk, the trunk members (switch ports) take on certain settings necessary for correct operation of the trunking feature.

Before you configure your trunk, you must consider these settings, along with specific configuration rules, as follows:

1. Read the configuration rules provided in the section, [“Static Trunk Group Configuration Rules” on page 145](#).
2. Determine which switch ports (up to 16) are to become *trunk members* (the specific ports making up the trunk).
3. Ensure that the chosen switch ports are set to **enabled**. Trunk member ports must have the same VLAN and Spanning Tree configuration.
4. Consider how the existing Spanning Tree will react to the new trunk configuration. See [Chapter 11, “Spanning Tree Protocols,”](#) for Spanning Tree Group configuration guidelines.
5. Consider how existing VLANs will be affected by the addition of a trunk.

Static Trunk Group Configuration Rules

The trunking feature operates according to specific configuration rules. When creating trunks, consider the following rules that determine how a trunk group reacts in any network topology:

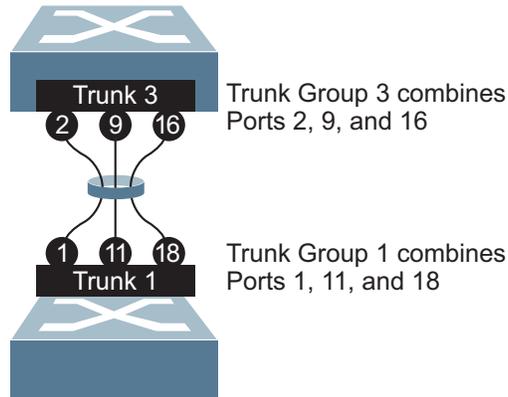

- All trunks must originate from one logical device, and lead to one logical destination device. Usually, a trunk connects two physical devices together with multiple links. However, in some networks, a single logical device may include multiple physical devices or when using VLAGs (see [“Virtual Link Aggregation Groups” on page 175](#)). In such cases, links in a trunk are allowed to connect to multiple physical devices because they act as one logical device.
- Any physical switch port can belong to only one trunk group.
- Trunking from third-party devices must comply with Cisco® EtherChannel® technology.
- All ports in a trunk must have the same link configuration (speed, duplex, flow control), the same VLAN properties, and the same Spanning Tree, storm control, and ACL configuration. It is recommended that the ports in a trunk be members of the same VLAN.
- Each trunk inherits its port configuration (speed, flow control, tagging) from the first member port. As additional ports are added to the trunk, their settings must be changed to match the trunk configuration.
- When a port leaves a trunk, its configuration parameters are retained.
- You cannot configure a trunk member as a monitor port in a port-mirroring configuration.

- Trunks cannot be monitored by a monitor port; however, trunk members can be monitored.

Configuring a Static Port Trunk

In the following example, three ports are trunked between two switches.

Figure 9. Port Trunk Group Configuration Example

Before configuring each switch in this example, you must connect to the appropriate switches as the administrator.

Note: For details about accessing and using any of the commands described in this example, see the *RackSwitch G8264CS ISCLI Reference*.

1. Follow these steps on the G8264CS:
 - a. Define a trunk group.

```
RS 8264CS(config)# portchannel 3 port 2,9,16
RS 8264CS(config)# portchannel 3 enable
```

- b. Verify the configuration.

```
# show portchannel information
```

Examine the resulting information. If any settings are incorrect, make appropriate changes.

2. Repeat the process on the other switch.

```
RS 8264CS(config)# portchannel 1 port 1,11,18
RS 8264CS(config)# portchannel 1 enable
```

3. Connect the switch ports that will be members in the trunk group.

Trunk group 3 (on the G8264CS) is now connected to trunk group 1 (on the other switch).

Note: In this example, two G8264CS switches are used. If a third-party device supporting link aggregation is used (such as Cisco routers and switches with Ether-Channel technology or Sun's Quad Fast Ethernet Adapter), trunk groups on the third-party device must be configured manually. Connection problems could arise when using automatic trunk group negotiation on the third-party device.

4. Examine the trunking information on each switch.

```
# show portchannel information
PortChannel 3: Enabled
Protocol-Static
port state:
  2: STG 1 forwarding
  9: STG 1 forwarding
 16: STG 1 forwarding
```

Information about each port in each configured trunk group is displayed. Make sure that trunk groups consist of the expected ports and that each port is in the expected state.

The following restrictions apply:

- Any physical switch port can belong to only one trunk group.
- Up to 16 ports can belong to the same trunk group.
- All ports in static trunks must have the same link configuration (speed, duplex, flow control).
- Trunking from third-party devices must comply with Cisco® EtherChannel® technology.

Link Aggregation Control Protocol

Link Aggregation Control Protocol (LACP) is an IEEE 802.3ad standard for grouping several physical ports into one logical port (known as a dynamic trunk group or Link Aggregation group) with any device that supports the standard. Please refer to IEEE 802.3ad-2002 for a full description of the standard.

The 802.3ad standard allows standard Ethernet links to form a single Layer 2 link using the Link Aggregation Control Protocol (LACP). Link aggregation is a method of grouping physical link segments of the same media type and speed in full duplex, and treating them as if they were part of a single, logical link segment. If a link in a LACP trunk group fails, traffic is reassigned dynamically to the remaining link(s) of the dynamic trunk group.

Note: LACP implementation in the Lenovo Networking OS does not support the Churn machine, an option used to detect if the port is operable within a bounded time period between the actor and the partner. Only the Marker Responder is implemented, and there is no marker protocol generator.

A port's Link Aggregation Identifier (LAG ID) determines how the port can be aggregated. The Link Aggregation ID (LAG ID) is constructed mainly from the partner switch's *system ID* and the port's *admin key*, as follows:

- **System ID:** an integer value based on the partner switch's MAC address and the system priority assigned in the CLI.
- **Admin key:** a port's Admin key is an integer value (1-65535) that you can configure in the CLI. Each switch port that participates in the same LACP trunk group must have the same *admin key* value. The Admin key is *local significant*, which means the partner switch does not need to use the same Admin key value.

For example, consider two switches, an Actor (the G8264CS) and a Partner (another switch), as shown in [Table 17](#).

Table 17. Actor vs. Partner LACP configuration

Actor Switch	Partner Switch	
Port 7 (admin key = 100)	Port 1 (admin key = 50)	Primary trunk group
Port 8 (admin key = 100)	Port 2 (admin key = 50)	Primary trunk group
Port 9 (admin key = 100)	Port 3 (admin key = 70)	Secondary trunk group
Port 10 (admin key = 100)	Port 4 (admin key = 70)	Secondary trunk group

In the configuration shown in [Table 17](#), Actor switch ports 7 and 8 aggregate to form an LACP trunk group with Partner switch ports 1 and 2. Only ports with the same LAG ID are aggregated in the trunk group. Actor switch ports 9 and 10 are not aggregated in the same trunk group, because although they have the same admin key on the Actor switch, their LAG IDs are different (due to a different Partner switch admin key configuration). Instead, they form a secondary trunk group with Partner switch ports 3 and 4.

LACP automatically determines which member links can be aggregated and then aggregates them. It provides for the controlled addition and removal of physical links for the link aggregation.

Static LACP Trunks

To prevent switch ports with the same admin key from forming multiple trunk groups, you can configure the LACP trunk as static. In a static LACP trunk, ports with the same admin key, but with different LAG IDs, compete to get aggregated in a trunk group. The LAG ID for the trunk group is decided based on the first port that is aggregated in the group. Ports with this LAG ID get aggregated and the other ports are placed in suspended mode. As per the configuration shown in [Table 17](#), if port 7 gets aggregated first, then the LAG ID of port 7 would be the LAG ID of the trunk. Port 8 will join the trunk while ports 9 and 10 would be placed in suspended mode. When in suspended mode, a port transmits only LACP data units (LACPDUs) and discards all other traffic.

A port may also be placed in suspended mode for the following reasons:

- When LACP is configured on the port but it stops receiving LACPDUs from the partner switch.
- When the port has a different LAG ID because of the partner switch MAC or port LACP key being different. For example: when a switch is connected to two partners.

Static LACP trunks are configured by associating the LACP admin key to a portchannel ID within a dedicated LACP portchannel group range:

```
RS 8264CS(config)# portchannel <65-128> lacp key <adminkey of the LAG>
```

LACP Port Modes

Up to 64 ports can be assigned to a single LAG, but only 16 ports can actively participate in the LAG at a given time.

Each port on the switch can have one of the following LACP modes.

- off (default)
The user can configure this port in to a regular static trunk group.
- active
The port is capable of forming an LACP trunk. This port sends LACPDU packets to partner system ports.
- passive
The port is capable of forming an LACP trunk. This port only responds to the LACPDU packets sent from an LACP *active* port.

Each active LACP port transmits LACP data units (LACPDUs), while each passive LACP port listens for LACPDUs. During LACP negotiation, the admin key is exchanged. The LACP trunk group is enabled as long as the information matches at both ends of the link. If the admin key value changes for a port at either end of the link, that port's association with the LACP trunk group is lost.

When the system is initialized, all ports by default are in LACP *off* mode and are assigned unique *admin keys*. To make a group of ports aggregatable, you assign them all the same *admin key*. You must set the port's LACP mode to *active* to activate LACP negotiation. You can set other port's LACP mode to passive, to reduce the amount of LACPDU traffic at the initial trunk-forming stage.

Use the following command to check whether the ports are trunked:

```
RS 8264CS # show lacp information
```

Note: If you configure LACP on ports with 802.1X network access control, make sure the ports on both sides of the connection are properly configured for both LACP and 802.1X.

LACP Individual

Ports assigned with an LACP admin key are prevented by default from forming individual links if they cannot join an LACP trunk group. To override this behavior, use the following commands:

```
RS 8264CS(config) # interface port <port number>  
RS 8264CS(config-if) # no lacp suspend-individual
```

This allows the selected ports to be treated as normal link-up ports, which may forward data traffic according to STP, Hot Links or other applications, if they do not receive any LACPDUs.

To configure the LACP individual setting for all the ports in a static LACP trunk, use the following commands:

```
RS 8264CS(config)# interface portchannel lacp <adminkey of the LAG>  
RS 8264CS(config-PortChannel)# [no] lacp suspend-individual
```

or:

```
RS 8264CS(config)# interface portchannel <static trunk ID of the LAG>  
RS 8264CS(config-PortChannel)# [no] lacp suspend-individual
```

LACP Minimum Links Option

For dynamic trunks that require a guaranteed amount of bandwidth to be considered useful, you can specify the minimum number of links for the trunk. If the specified minimum number of ports are not available, the trunk link will not be established. If an active LACP trunk loses one or more component links, the trunk will be placed in the down state if the number of links falls to less than the specified minimum. By default, the minimum number of links is 1, meaning that LACP trunks will remain operational as long as at least one link is available.

The LACP minimum links setting can be configured as follows:

- Via interface configuration mode:

```
RS 8264CS(config)# interface port <port number or range>
RS 8264CS(config-if)# port-channel min-links <minimum links>
RS 8264CS(config-if)# exit
```

- Or via portchannel configuration mode:

```
RS 8264CS(config)# interface portchannel lacp <LACP key>
RS 8264CS(config-PortChannel)# port-channel min-links <minimum links>
RS 8264CS(config-if)# exit
```

Configuring LACP

Use the following procedure to configure LACP for ports 7, 8, 9 and 10 to participate in link aggregation.

1. Configure port parameters. All ports that participate in the LACP trunk group must have the same settings, including VLAN membership.
2. Select the port range and define the admin key. Only ports with the same admin key can form an LACP trunk group.

```
RS 8264CS(config)# interface port 7-10
RS 8264CS(config-if)# lacp key 100
```

3. Set the LACP mode.

```
RS 8264CS(config-if)# lacp mode active
```

4. Allow member ports to individually participate in normal data traffic if no LACPDUs are received.

```
RS 8264CS(config-if)# no lacp suspend-individual
RS 8264CS(config-if)# exit
```

5. Set the link aggregation as static, by associating it with trunk ID 65:

```
RS 8264CS(config)# portchannel 65 lacp key 100
```

Configurable Trunk Hash Algorithm

Traffic in a trunk group is statistically distributed among member ports using a *hash* process where various address and attribute bits from each transmitted frame are recombined to specify the particular trunk port the frame will use.

The switch can be configured to use a variety of hashing options. To achieve the most even traffic distribution, select options that exhibit a wide range of values for your particular network. Avoid hashing on information that is not usually present in the expected traffic, or which does not vary.

The G8264CS supports the following hashing options:

- Layer 2 source MAC address

```
RS 8264CS(config)# portchannel thash l2thash l2-source-mac-address
```

- Layer 2 destination MAC address

```
RS 8264CS(config)# portchannel thash l2thash  
l2-destination-mac-address
```

- Layer 2 source and destination MAC address

```
RS 8264CS(config)# portchannel thash l2thash l2-source-destination-mac
```

- Layer 3 IPv4/IPv6 source IP address

```
RS 8264CS(config)# portchannel thash l3thash l3-source-ip-address
```

- Layer 3 IPv4/IPv6 destination IP address

```
RS 8264CS(config)# portchannel thash l3thash l3-destination-ip-address
```

Layer 3 source and destination IPv4/IPv6 address (the default) The G8264CS

```
RS 8264CS(config)# portchannel thash l3thash l3-source-destination-ip
```

supports the following FCoE hashing options:

```
RS 8264CS(config)# portchannel thash fcoe cntag-id  
RS 8264CS(config)# portchannel thash fcoe destination-id  
RS 8264CS(config)# portchannel thash fcoe fabric-id  
RS 8264CS(config)# portchannel thash fcoe originator-id  
RS 8264CS(config)# portchannel thash fcoe responder-id  
RS 8264CS(config)# portchannel thash fcoe source-id
```

Chapter 11. Spanning Tree Protocols

When multiple paths exist between two points on a network, Spanning Tree Protocol (STP), or one of its enhanced variants, can prevent broadcast loops and ensure that the RackSwitch G8264CS (G8264CS) uses only the most efficient network path.

This chapter covers the following topics:

- [“Spanning Tree Protocol Modes” on page 154](#)
- [“Global STP Control” on page 155](#)
- [“PVRST Mode” on page 155](#)
- [“Rapid Spanning Tree Protocol” on page 168](#)
- [“Multiple Spanning Tree Protocol” on page 170](#)
- [“Port Type and Link Type” on page 174](#)

Spanning Tree Protocol Modes

Lenovo Networking OS 8.2 supports the following STP modes:

- Rapid Spanning Tree Protocol (RSTP)

IEEE 802.1D (2004) RSTP allows devices to detect and eliminate logical loops in a bridged or switched network. When multiple paths exist, STP configures the network so that only the most efficient path is used. If that path fails, STP automatically configures the best alternative active path on the network to sustain network operations. RSTP is an enhanced version of IEEE 802.1D (1998) STP, providing more rapid convergence of the Spanning Tree network path states on STG 1.

See [“Rapid Spanning Tree Protocol” on page 168](#) for details.

- Per-VLAN Rapid Spanning Tree (PVRST)

PVRST mode is based on RSTP to provide rapid Spanning Tree convergence, but supports instances of Spanning Tree, allowing one STG per VLAN. PVRST mode is compatible with Cisco R-PVST/R-PVST+ mode.

PVRST is the default Spanning Tree mode on the G8264CS. See [“PVRST Mode” on page 155](#) for details.

- Multiple Spanning Tree Protocol (MSTP)

IEEE 802.1Q (2003) MSTP provides both rapid convergence and load balancing in a VLAN environment. MSTP allows multiple STGs, with multiple VLANs in each.

See [“Multiple Spanning Tree Protocol” on page 170](#) for details.

Global STP Control

By default, the Spanning Tree feature is globally enabled on the switch, and is set for PVRST mode. Spanning Tree (and thus any currently configured STP mode) can be globally disabled using the following command:

```
RS 8264CS(config)# spanning-tree mode disable
```

Spanning Tree can be re-enabled by specifying the STP mode:

```
RS 8264CS(config)# spanning-tree mode {pvrst|rstp|mst}
```

where the command options represent the following modes:

- rstp: RSTP mode
- pvrst: PVRST mode
- mst: MSTP mode

PVRST Mode

Note: Per-VLAN Rapid Spanning Tree (PVRST) is enabled by default on the G8264CS.

Using STP, network devices detect and eliminate logical loops in a bridged or switched network. When multiple paths exist, Spanning Tree configures the network so that a switch uses only the most efficient path. If that path fails, Spanning Tree automatically sets up another active path on the network to sustain network operations.

N/OS PVRST mode is based on IEEE 802.1w RSTP. Like RSTP, PVRST mode provides rapid Spanning Tree convergence. However, PVRST mode is enhanced for multiple instances of Spanning Tree. In PVRST mode, each VLAN may be automatically or manually assigned to one of 127 available STGs. Each STG acts as an independent, simultaneous instance of STP. PVRST uses IEEE 802.1Q tagging to differentiate STP BPDUs and is compatible with Cisco R-PVST/R-PVST+ modes.

The relationship between ports, trunk groups, VLANs, and Spanning Trees is shown in [Table 18](#).

Table 18. *Ports, Trunk Groups, and VLANs*

Switch Element	Belongs To
Port	Trunk group or one or more VLANs
Trunk group	One or more VLANs
VLAN (non-default)	<ul style="list-style-type: none">● PVRST: One VLAN per STG● RSTP: All VLANs are in STG 1● MSTP: Multiple VLANs per STG

Port States

The port state controls the forwarding and learning processes of Spanning Tree. In PVRST, the port state has been consolidated to the following: discarding, learning, and forwarding.

Due to the sequence involved in these STP states, considerable delays may occur while paths are being resolved. To mitigate delays, ports defined as *edge* ports (“Port Type and Link Type” on page 174) may bypass the discarding and learning states, and enter directly into the forwarding state.

Bridge Protocol Data Units

Bridge Protocol Data Units Overview

To create a Spanning Tree, the switch generates a configuration Bridge Protocol Data Unit (BPDU), which it then forwards out of its ports. All switches in the Layer 2 network participating in the Spanning Tree gather information about other switches in the network through an exchange of BPDUs.

A bridge sends BPDU packets at a configurable regular interval (2 seconds by default). The BPDU is used to establish a path, much like a hello packet in IP routing. BPDUs contain information about the transmitting bridge and its ports, including bridge MAC addresses, bridge priority, port priority, and path cost. If the ports are in trunk mode/tagged, each port sends out a special BPDU containing the tagged information.

The generic action of a switch on receiving a BPDU is to compare the received BPDU to its own BPDU that it will transmit. If the priority of the received BPDU is better than its own priority, it will replace its BPDU with the received BPDU. Then, the switch adds its own bridge ID number and increments the path cost of the BPDU. The switch uses this information to block any necessary ports.

Note: If STP is globally disabled, BPDUs from external devices will transit the switch transparently. If STP is globally enabled, for ports where STP is turned off, inbound BPDUs will instead be discarded.

Determining the Path for Forwarding BPDUs

When determining which port to use for forwarding and which port to block, the G8264CS uses information in the BPDU, including each bridge ID. A technique based on the “lowest root cost” is then computed to determine the most efficient path for forwarding.

Bridge Priority

The bridge priority parameter controls which bridge on the network is the STG root bridge. To make one switch become the root bridge, configure the bridge priority lower than all other switches and bridges on your network. The lower the value, the higher the bridge priority. Use the following command to configure the bridge priority:

```
RS 8264CS(config)# spanning-tree stp <STGs> bridge priority <0-65535>
```

Port Priority

The port priority helps determine which bridge port becomes the root port or the designated port. The case for the root port is when two switches are connected using a minimum of two links with the same path-cost. The case for the designated port is in a network topology that has multiple bridge ports with the same path-cost connected to a single segment, the port with the lowest port priority becomes the designated port for the segment. Use the following command to configure the port priority:

```
RS 8264CS(config-if)# spanning-tree stp <STGs> priority <port priority>
```

where *priority value* is a number from 0 to 240, in increments of 16 (such as 0, 16, 32, and so on). If the specified priority value is not evenly divisible by 16, the value will be automatically rounded down to the nearest valid increment whenever manually changed in the configuration, or whenever a configuration file from a release prior to N/OS 6.5 is loaded.

Root Guard

The root guard feature provides a way to enforce the root bridge placement in the network. It keeps a new device from becoming root and thereby forcing STP re-convergence. If a root-guard enabled port detects a root device, that port will be placed in a blocked state.

You can configure the root guard at the port level using the following commands:

```
RS 8264CS(config)# interface port <port number>
RS 8264CS(config-if)# spanning-tree guard root
```

The default state is “none”, i.e. disabled.

Loop Guard

In general, STP resolves redundant network topologies into loop-free topologies. The loop guard feature performs additional checking to detect loops that might not be found using Spanning Tree. STP loop guard ensures that a non-designated port does not become a designated port.

To globally enable loop guard, enter the following command:

```
RS 8264CS(config)# spanning-tree loopguard
```

Note: The global loop guard command will be effective on a port only if the port-level loop guard command is set to default as shown below:

```
RS 8264CS(config)# interface port <port number>
RS 8264CS(config-if)# no spanning-tree guard
```

To enable loop guard at the port level, enter the following command:

```
RS 8264CS(config)# interface port <port number>
RS 8264CS(config-if)# spanning-tree guard loop
```

The default state is “none”, meaning disabled.

Port Path Cost

The port path cost assigns lower values to high-bandwidth ports, such as 10 Gigabit Ethernet, to encourage their use. The objective is to use the fastest links so that the route with the lowest cost is chosen. A value of 0 (the default) indicates that the default cost will be computed for an auto-negotiated link or trunk speed.

Use the following command to modify the port path cost:

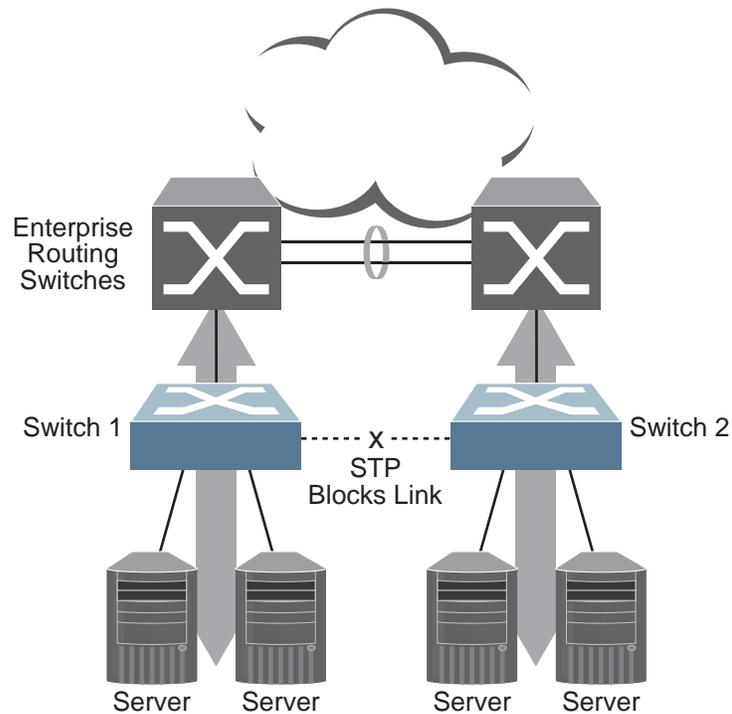

```
RS 8264CS(config)# interface port <port number>  
RS 8264CS(config-if)# spanning-tree stp <STGs> path-cost <path cost value>  
RS 8264CS(config-if)# exit
```

The port path cost can be a value from 1 to 200000000. Specify 0 for automatic path cost.

Simple STP Configuration

Figure 10 depicts a simple topology using a switch-to-switch link between two G8264CS 1 and 2.

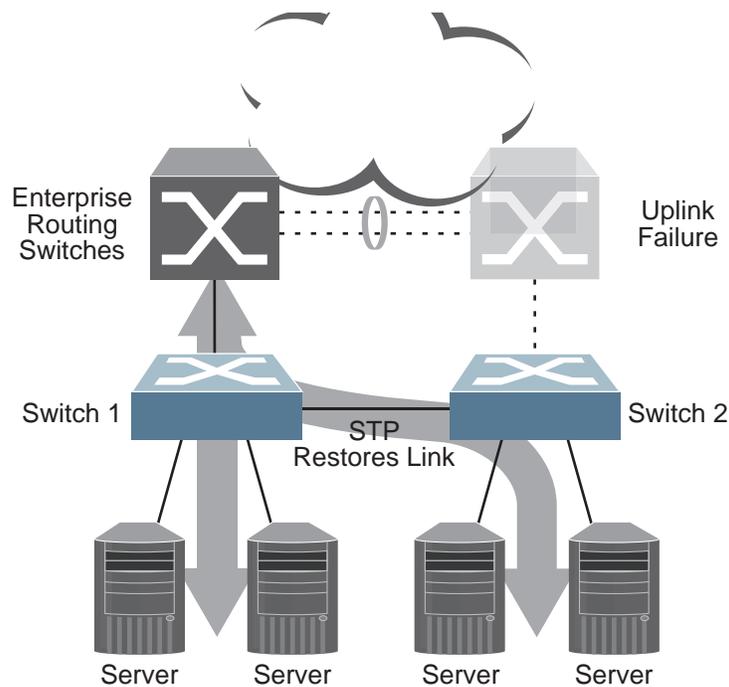

Figure 10. Spanning Tree Blocking a Switch-to-Switch Link

To prevent a network loop among the switches, STP must block one of the links between them. In this case, it is desired that STP block the link between the Lenovo switches, and not one of the G8264CS uplinks or the Enterprise switch trunk.

During operation, if one G8264CS experiences an uplink failure, STP will activate the Lenovo switch-to-switch link so that server traffic on the affected G8264CS may pass through to the active uplink on the other G8264CS, as shown in Figure 11.

Figure 11. Spanning Tree Restoring the Switch-to-Switch Link

In this example, port 10 on each G8264CS is used for the switch-to-switch link. To ensure that the G8264CS switch-to-switch link is blocked during normal operation, the port path cost is set to a higher value than other paths in the network. To configure the port path cost on the switch-to-switch links in this example, use the following commands on each G8264CS.

```
RS 8264CS(config)# interface port 10
RS 8264CS(config-if)# spanning-tree stp 1 path-cost 60000
RS 8264CS(config-if)# exit
```

Per-VLAN Spanning Tree Groups

PVRST mode supports a maximum of 127 STGs, with each STG acting as an independent, simultaneous instance of STP.

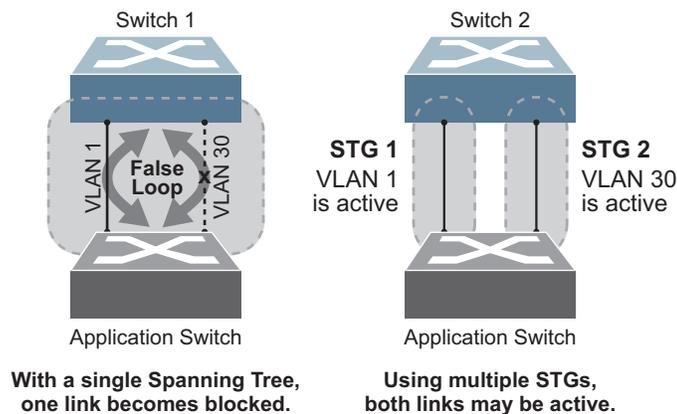

Multiple STGs provide multiple data paths which can be used for load-balancing and redundancy. To enable load balancing between two G8264CSs using multiple STGs, configure each path with a different VLAN and then assign each VLAN to a separate STG. Since each STG is independent, they each send their own IEEE 802.1Q tagged Bridge Protocol Data Units (BPDUs).

Each STG behaves as a bridge group and forms a loop-free topology. The default STG 1 may contain multiple VLANs (typically until they can be assigned to another STG). STGs 2-127 may contain only one VLAN each.

Using Multiple STGs to Eliminate False Loops

Figure 12 shows a simple example of why multiple STGs are needed. In the figure, two ports on a G8264CS are connected to two ports on an application switch. Each of the links is configured for a different VLAN, preventing a network loop. However, in the first network, since a single instance of Spanning Tree is running on all the ports of the G8264CS, a physical loop is assumed to exist, and one of the VLANs is blocked, impacting connectivity even though no actual loop exists.

Figure 12. Using Multiple Instances of Spanning Tree Group

In the second network, the problem of improper link blocking is resolved when the VLANs are placed into different Spanning Tree Groups (STGs). Since each STG has its own independent instance of Spanning Tree, each STG is responsible only for the loops within its own VLAN. This eliminates the false loop, and allows both VLANs to forward packets between the switches at the same time.

VLANs and STG Assignment

In PVRST mode, up to 128 STGs are supported. Ports cannot be added directly to an STG. Instead, ports must be added as members of a VLAN, and the VLAN must then be assigned to the STG.

STG 1 is the default STG. Although VLANs can be added to or deleted from default STG 1, the STG itself cannot be deleted from the system. By default, STG 1 is enabled and includes VLAN 1, which by default includes all switch ports (except for management VLANs and management ports).

STG 128 is reserved for switch management. By default, STG 128 is disabled, but includes management VLAN 4095 and the management port.

By default, all other STGs (STG 2 through 127) are enabled, though they initially include no member VLANs. VLANs must be assigned to STGs. By default, this is done automatically using VLAN Automatic STG Assignment (VASA), though it can also be done manually (see [“Manually Assigning STGs” on page 162](#)).

When VASA is enabled (as by default), each time a new VLAN is configured, the switch will automatically assign that new VLAN to its own STG. Conversely, when a VLAN is deleted, if its STG is not associated with any other VLAN, the STG is returned to the available pool.

The specific STG number to which the VLAN is assigned is based on the VLAN number itself. For low VLAN numbers (1 through 127), the switch will attempt to assign the VLAN to its matching STG number. For higher numbered VLANs, the STG assignment is based on a simple modulus calculation; the attempted STG number will “wrap around,” starting back at the top of STG list each time the end of the list is reached. However, if the attempted STG is already in use, the switch will select the next available STG. If an empty STG is not available when creating a new VLAN, the VLAN is automatically assigned to default STG 1.

If ports are tagged, each tagged port sends out a special BPDU containing the tagged information. Also, when a tagged port belongs to more than one STG, the egress BPDUs are tagged to distinguish the BPDUs of one STG from those of another STG.

VASA is enabled by default, but can be disabled or re-enabled using the following commands:

```
RS 8264CS(config)# [no] spanning-tree stg-auto
```

If VASA is disabled, when you create a new VLAN, that VLAN automatically belongs to default STG 1. To place the VLAN in a different STG, assign it manually.

VASA applies only to PVRST mode and is ignored in RSTP and MSTP modes.

Manually Assigning STGs

The administrator may manually assign VLANs to specific STGs, whether or not VASA is enabled.

1. If no VLANs exist (other than default VLAN 1), see [“Guidelines for Creating VLANs” on page 163](#) for information about creating VLANs and assigning ports to them.

2. Assign the VLAN to an STG using one of the following methods:
 - o From the global configuration mode:

```
RS 8264CS(config)# spanning-tree stp <STG numbers> vlan <VLAN>
```

- o Or from within the VLAN configuration mode:

```
RS 8264CS(config)# vlan <VLAN numbers>  
RS 8264CS(config-vlan)# stg <STG numbers>  
RS 8264CS(config-vlan)# exit
```

When a VLAN is assigned to a new STG, the VLAN is automatically removed from its prior STG.

Note: For proper operation with switches that use Cisco PVST+, it is recommended that you create a separate STG for each VLAN.

Guidelines for Creating VLANs

Follow these guidelines when creating VLANs:

- When you create a new VLAN, if VASA is enabled (the default), that VLAN is automatically assigned its own STG. If VASA is disabled, the VLAN automatically belongs to STG 1, the default STG. To place the VLAN in a different STG, see [“Manually Assigning STGs” on page 162](#). The VLAN is automatically removed from its old STG before being placed into the new STG.
- Each VLANs must be contained *within* a single STG; a VLAN cannot span multiple STGs. By confining VLANs within a single STG, you avoid problems with Spanning Tree blocking ports and causing a loss of connectivity within the VLAN. When a VLAN spans multiple switches, it is recommended that the VLAN remain within the same STG (be assigned the same STG ID) across all the switches.
- If ports are tagged, all trunked ports can belong to multiple STGs.
- A port cannot be directly added to an STG. The port must first be added to a VLAN, and that VLAN added to the desired STG.

Rules for VLAN Tagged/Trunk Mode Ports

The following rules apply to VLAN tagged ports:

- Tagged/trunk mode ports can belong to more than one STG, but untagged/access mode ports can belong to only one STG.
- When a tagged/trunk mode port belongs to more than one STG, the egress BPDUs are tagged to distinguish the BPDUs of one STG from those of another STG.

Adding and Removing Ports from STGs

The following rules apply when you add ports to or remove ports from STGs:

- When you add a port to a VLAN that belongs to an STG, the port is also added to that STG. However, if the port you are adding is an untagged port and is already a member of another STG, that port will be removed from its current STG and added to the new STG. An untagged port cannot belong to more than one STG.

For example: Assume that VLAN 1 belongs to STG 1, and that port 1 is untagged and does not belong to any STG. When you add port 1 to VLAN 1, port 1 will automatically become part of STG 1.

However, if port 5 is untagged and is a member of VLAN 3 in STG 2, then adding port 5 to VLAN 1 in STG 1 will change the port PVID from 3 to 1:

"Port 5 is an UNTAGGED/Access Mode port and its PVID/Native-VLAN changed from 3 to 1.

- When you remove a port from VLAN that belongs to an STG, that port will also be removed from the STG. However, if that port belongs to another VLAN in the same STG, the port remains in the STG.

As an example, assume that port 2 belongs to only VLAN 2, and that VLAN 2 belongs to STG 2. When you remove port 2 from VLAN 2, the port is moved to default VLAN 1 and is removed from STG 2.

However, if port 2 belongs to both VLAN 1 and VLAN 2, and both VLANs belong to STG 1, removing port 2 from VLAN 2 does not remove port 2 from STG 1, because the port is still a member of VLAN 1, which is still a member of STG 1.

- An STG cannot be deleted, only disabled. If you disable the STG while it still contains VLAN members, Spanning Tree will be off on all ports belonging to that VLAN.

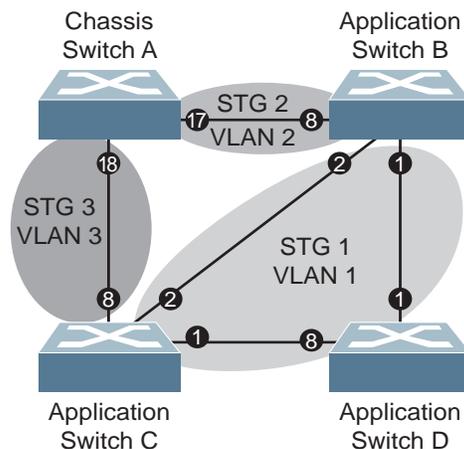

The relationship between port, trunk groups, VLANs, and Spanning Trees is shown in [Table 18 on page 155](#).

The Switch-Centric Model

PVRST is switch-centric: STGs are enforced only on the switch where they are configured. PVRST allows only one VLAN per STG, except for the default STG 1 to which multiple VLANs can be assigned. The STG ID is not transmitted in the Spanning Tree BPDU. Each Spanning Tree decision is based entirely on the configuration of the particular switch.

For example, in [Figure 13](#), each switch is responsible for the proper configuration of its own ports, VLANs, and STGs. Switch A identifies its own port 17 as part of VLAN 2 on STG 2, and the Switch B identifies its own port 8 as part of VLAN 2 on STG 2.

Figure 13. Implementing Multiple Spanning Tree Groups

The VLAN participation for each Spanning Tree Group in [Figure 13 on page 165](#) is as follows:

- VLAN 1 Participation

Assuming Switch B to be the root bridge, Switch B transmits the BPDU for STG 1 on ports 1 and 2. Switch C receives the BPDU on port 2, and Switch D receives the BPDU on port 1. Because there is a network loop between the switches in VLAN 1, either Switch D will block port 8 or Switch C will block port 1, depending on the information provided in the BPDU.

- VLAN 2 Participation

Switch B, the root bridge, generates a BPDU for STG 2 from port 8. Switch A receives this BPDU on port 17, which is assigned to VLAN 2, STG 2. Because switch B has no additional ports participating in STG 2, this BPDU is not forwarded to any additional ports and Switch B remains the designated root.

- VLAN 3 Participation

For VLAN 3, Switch A or Switch C may be the root bridge. If Switch A is the root bridge for VLAN 3, STG 3, then Switch A transmits the BPDU from port 18. Switch C receives this BPDU on port 8 and is identified as participating in VLAN 3, STG 3. Since Switch C has no additional ports participating in STG 3, this BPDU is not forwarded to any additional ports and Switch A remains the designated root.

Configuring Multiple STGs

This configuration shows how to configure the three instances of STGs on the switches A, B, C, and D illustrated in [Figure 13 on page 165](#).

Because VASA is enabled by default, each new VLAN is automatically assigned its own STG.

1. Set the Spanning Tree mode on each switch to PVRST.

```
RS 8264CS(config)# spanning-tree mode pvrst
```

Note: PVRST is the default mode on the G8264CS. This step is not required unless the STP mode has been previously changed, and is shown here merely as an example of manual configuration.

2. Configure the following on Switch A:

Enable VLAN 2 and VLAN 3.

```
RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# exit
```

If VASA is disabled, enter the following commands:

```
RS 8264CS(config)# spanning-tree stp 2 vlan 2
RS 8264CS(config)# spanning-tree stp 3 vlan 3
```

Add port 17 to VLAN 2, port 18 to VLAN 3.

```
RS 8264CS(config)# interface port 17
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 18
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan 3
RS 8264CS(config-if)# exit
```

VLAN 2 and VLAN 3 are removed from STG 1.

Note: In PVRST mode, each instance of STG is enabled by default.

3. Configure the following on Switch B:

Add port 8 to VLAN 2. Ports 1 and 2 are by default in VLAN 1 assigned to STG 1.

```
RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# stg 2
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 8
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan 2
RS 8264CS(config-if)# exit
```

If VASA is disabled, enter the following command:

```
RS 8264CS(config)# spanning-tree stp 2 vlan 2
```

VLAN 2 is automatically removed from STG 1. By default VLAN 1 remains in STG 1.

4. Configure the following on application switch C:

Add port 8 to VLAN 3. Ports 1 and 2 are by default in VLAN 1 assigned to STG 1.

```
RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# stg 3
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 8
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan 3
RS 8264CS(config-if)# exit
```

If VASA is disabled, enter the following command:
RS 8264CS(config)# **spanning-tree stp 3 vlan 3**

VLAN 3 is automatically removed from STG 1. By default VLAN 1 remains in STG 1.

5. Switch D does not require any special configuration for multiple Spanning Trees. Switch D uses default STG 1 only.

Rapid Spanning Tree Protocol

RSTP provides rapid convergence of the Spanning Tree and provides the fast re-configuration critical for networks carrying delay-sensitive traffic such as voice and video. RSTP significantly reduces the time to reconfigure the active topology of the network when changes occur to the physical topology or its configuration parameters. RSTP reduces the bridged-LAN topology to a single Spanning Tree.

RSTP was originally defined in IEEE 802.1w (2001) and was later incorporated into IEEE 802.1D (2004), superseding the original STP standard.

RSTP parameters apply only to Spanning Tree Group (STG) 1. The PVRST mode STGs 2-128 are not used when the switch is placed in RSTP mode.

RSTP is compatible with devices that run IEEE 802.1D (1998) Spanning Tree Protocol. If the switch detects IEEE 802.1D (1998) BPDUs, it responds with IEEE 802.1D (1998)-compatible data units. RSTP is not compatible with Per-VLAN Rapid Spanning Tree (PVRST) protocol.

Port States

RSTP port state controls are the same as for PVRST: discarding, learning, and forwarding.

Due to the sequence involved in these STP states, considerable delays may occur while paths are being resolved. To mitigate delays, ports defined as *edge/portfast* ports ([“Port Type and Link Type” on page 174](#)) may bypass the discarding and learning states, and enter directly into the forwarding state.

RSTP Configuration Guidelines

This section provides important information about configuring RSTP. When RSTP is turned on, the following occurs:

- STP parameters apply only to STG 1.
- Only STG 1 is available. All other STGs are turned off.
- All VLANs, including management VLANs, are moved to STG 1.

RSTP Configuration Example

This section provides steps to configure RSTP.

1. Configure port and VLAN membership on the switch.
2. Set the Spanning Tree mode to Rapid Spanning Tree.

```
RS 8264CS(config)# spanning-tree mode rstp
```

3. Configure RSTP parameters.

```
RS 8264CS(config)# spanning-tree stp 1 bridge priority 8192
RS 8264CS(config)# spanning-tree stp 1 bridge hello-time 5
RS 8264CS(config)# spanning-tree stp 1 bridge forward-delay 20
RS 8264CS(config)# spanning-tree stp 1 bridge maximum-age 30
RS 8264CS(config)# no spanning-tree stp 1 enable
```

4. Configure port parameters:

```
RS 8264CS(config)# interface port 3
RS 8264CS(config-if)# spanning-tree stp 1 priority 240
RS 8264CS(config-if)# spanning-tree stp 1 path-cost 500
RS 8264CS(config-if)# no spanning-tree stp 1 enable
RS 8264CS(config-if)# exit
```

Multiple Spanning Tree Protocol

Multiple Spanning Tree Protocol (MSTP) extends Rapid Spanning Tree Protocol (RSTP), allowing multiple Spanning Tree Groups (STGs) which may each include multiple VLANs. MSTP was originally defined in IEEE 802.1s (2002) and was later included in IEEE 802.1Q (2003).

In MSTP mode, the G8264CS supports up to 32 instances of Spanning Tree, corresponding to STGs 1-32, with each STG acting as an independent, simultaneous instance of RSTP.

MSTP allows frames assigned to different VLANs to follow separate paths, with each path based on an independent Spanning Tree instance. This approach provides multiple forwarding paths for data traffic, thereby enabling load-balancing, and reducing the number of Spanning Tree instances required to support a large number of VLANs.

Due to Spanning Tree's sequence of discarding, learning, and forwarding, lengthy delays may occur while paths are being resolved. Ports defined as *edge/portfast* ports ("[Port Type and Link Type](#)" on page 174) bypass the Discarding and Learning states, and enter directly into the Forwarding state.

Note: In MSTP mode, Spanning Tree for the management ports is turned off by default.

MSTP Region

A group of interconnected bridges that share the same attributes is called an MST region. Each bridge within the region must share the following attributes:

- Alphanumeric name
- Revision number
- VLAN-to STG mapping scheme

MSTP provides rapid re-configuration, scalability and control due to the support of regions, and multiple Spanning-Tree instances support within each region.

Common Internal Spanning Tree

The Common Internal Spanning Tree (CIST) or MST0 provides a common form of Spanning Tree Protocol, with one Spanning-Tree instance that can be used throughout the MSTP region. CIST allows the switch to interoperate with legacy equipment, including devices that run IEEE 802.1D (1998) STP.

CIST allows the MSTP region to act as a virtual bridge to other bridges outside of the region, and provides a single Spanning-Tree instance to interact with them.

CIST port configuration includes Hello time, path-cost, and interface priority. These parameters do not affect Spanning Tree Groups 1-32. They apply only when the CIST is used.

MSTP Configuration Guidelines

This section provides important information about configuring Multiple Spanning Tree Groups:

- When MSTP is turned on, the switch moves VLAN 1 and VLANs 33-128 to the CIST. When MSTP is turned off, the switch moves VLAN 1 and VLANs 33-128 from the CIST to STG 1.
- When you enable MSTP, you must configure the Region Name. A default version number of 1 is configured automatically.
- Each bridge in the region must have the same name, revision number, and VLAN mapping.

MSTP Configuration Examples

Example 1

This section provides steps to configure MSTP on the G8264CS.

1. Configure port and VLAN membership on the switch.
2. Configure Multiple Spanning Tree region parameters, and set the mode to MSTP.

```
RS 8264CS(config)# spanning-tree mst configuration(Enter MST configuration mode)
RS 8264CS(config-mst)# name <name>      (Define the Region name)
RS 8264CS(config-mst)# exit
RS 8264CS(config)# spanning-tree mode mst(Set mode to Multiple Spanning Trees)
```

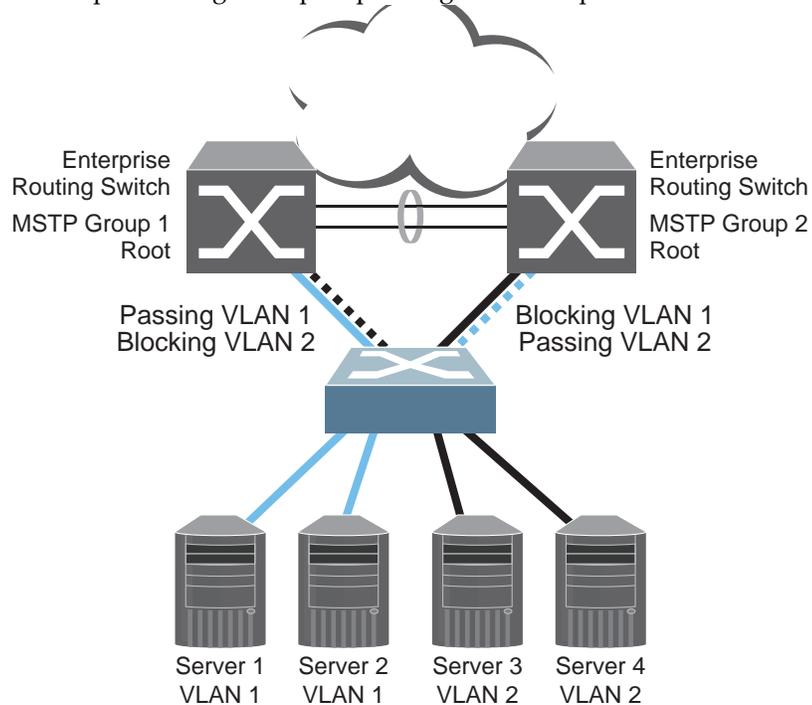

3. Map VLANs to MSTP instances:

```
RS 8264CS(config)# spanning-tree mst configuration( Enter MST configuration mode)
RS 8264CS(config-mst)# instance <instance ID> vlan <vlan number or range>
```

Example 2

This configuration shows how to configure MSTP Groups on the switch, as shown in [Figure 13](#).

Figure 14. Implementing Multiple Spanning Tree Groups

This example shows how multiple Spanning Trees can provide redundancy without wasting any uplink ports. In this example, the server ports are split between two separate VLANs. Both VLANs belong to two different MSTP groups. The Spanning Tree *priority* values are configured so that each routing switch is the root for a different MSTP instance. All of the uplinks are active, with each uplink port backing up the other.

1. Configure port membership and define the STGs for VLAN 1. Enable tagging on uplink ports that share VLANs. Port 19 and port 20 connect to the Enterprise Routing switches.

```
RS 8264CS(config)# interface port 19, 20
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

2. Configure MSTP: Spanning Tree mode, region name, and version.

```
RS 8264CS(config)# spanning-tree mst configuration
RS 8264CS(config-mst)# name MyRegion (Define the Region name)
RS 8264CS(config-mst)# revision 100 (Define the Revision level)
RS 8264CS(config-mst)# exit
RS 8264CS(config)# spanning-tree mode mst (Set mode to Multiple Spanning Trees)
```

3. Map VLANs to MSTP instances:

```
RS 8264CS(config)# spanning-tree mst configuration
RS 8264CS(config-mst)# instance 1 vlan 1
RS 8264CS(config-mst)# instance 2 vlan 2
```

4. Add server ports 1 and 2 to VLAN 1. Add uplink ports 19 and port 20 to VLAN 1.

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# switchport trunk allowed vlan 1
RS 8264CS(config-if)# exit
```

5. Configure port membership and define the STGs for VLAN 2. Add server ports 3, 4, and 5 to VLAN 2. Add uplink ports 19 and 20 to VLAN 2. Assign VLAN 2 to STG 2.

```
RS 8264CS(config)# interface port 3,4,5
RS 8264CS(config-if)# switchport trunk allowed vlan 2
RS 8264CS(config-if)# exit
```

Note: Each STG is enabled by default.

Port Type and Link Type

Edge/Portfast Port

A port that does not connect to a bridge is called an *edge port*. Since edge ports are assumed to be connected to non-STP devices (such as directly to hosts or servers), they are placed in the forwarding state as soon as the link is up.

Edge ports send BPDUs to upstream STP devices like normal STP ports, but do not receive BPDUs. If a port with `edge` enabled does receive a BPDU, it immediately begins working as a normal (non-edge) port, and participates fully in Spanning Tree.

Use the following commands to define or clear a port as an edge port:

```
RS 8264CS(config)# interface port <port>
RS 8264CS(config-if)# [no] spanning-tree portfast
RS 8264CS(config-if)# exit
```

Link Type

The link type determines how the port behaves in regard to Rapid Spanning Tree. Use the following commands to define the link type for the port:

```
RS 8264CS(config)# interface port <port>
RS 8264CS(config-if)# [no] spanning-tree link-type <type>
RS 8264CS(config-if)# exit
```

where *type* corresponds to the duplex mode of the port, as follows:

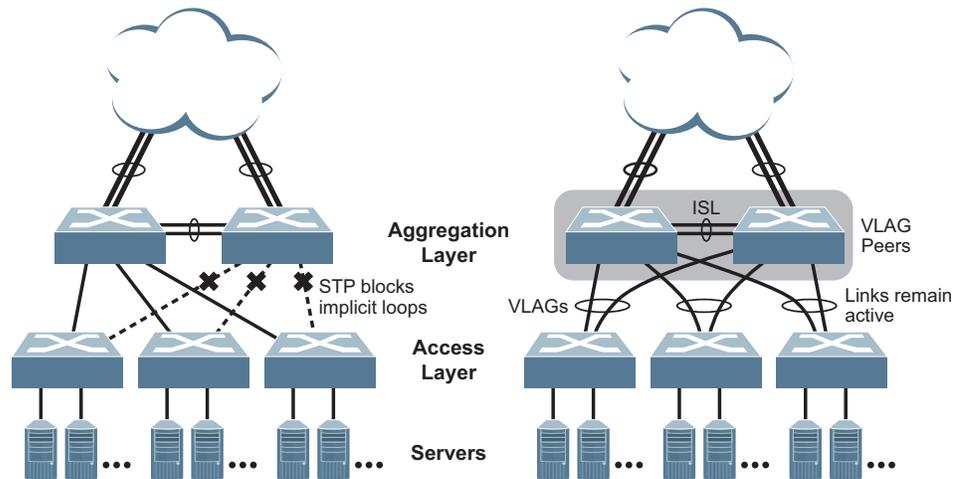

- `p2p` A full-duplex link to another device (point-to-point)
- `shared` A half-duplex link is a shared segment and can contain more than one device.
- `auto` The switch dynamically configures the link type.

Note: Any STP port in full-duplex mode can be manually configured as a shared port when connected to a non-STP-aware shared device (such as a typical Layer 2 switch) used to interconnect multiple STP-aware devices.

Chapter 12. Virtual Link Aggregation Groups

In many data center environments, downstream servers or switches connect to upstream devices which consolidate traffic. For example, see [Figure 15](#).

Figure 15. Typical Data Center Switching Layers with STP vs. VLAG

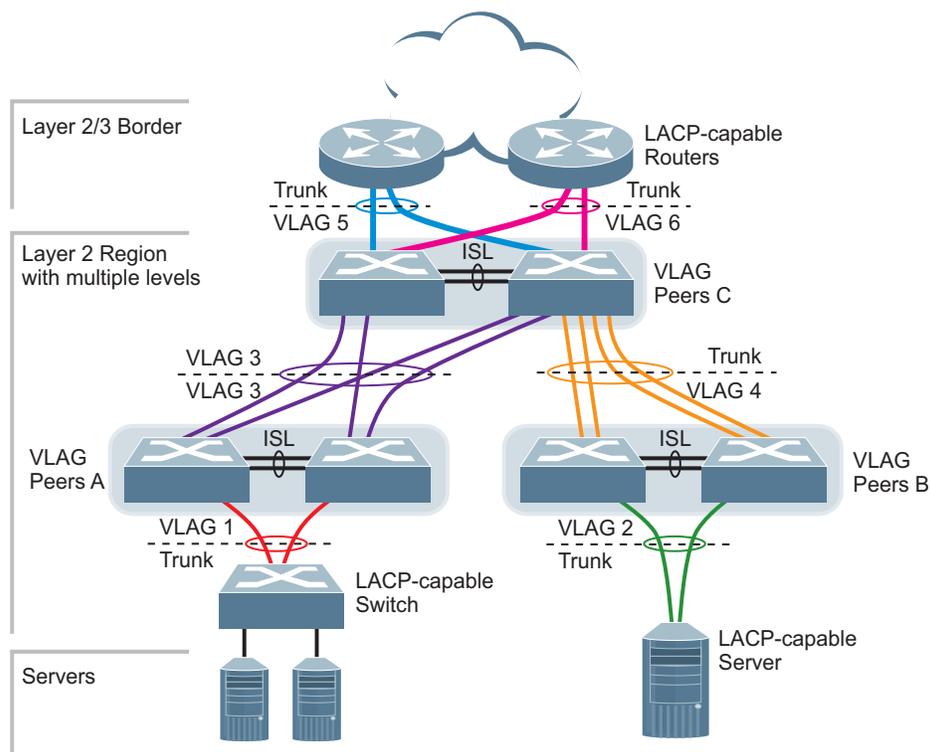

As shown in the example, a switch in the access layer may be connected to more than one switch in the aggregation layer to provide for network redundancy. Typically, Spanning Tree Protocol (RSTP, PVRST, or MSTP—see [“Spanning Tree Protocols” on page 153](#)) is used to prevent broadcast loops, blocking redundant uplink paths. This has the unwanted consequence of reducing the available bandwidth between the layers by as much as 50%. In addition, STP may be slow to resolve topology changes that occur during a link failure, and can result in considerable MAC address flooding.

Using Virtual Link Aggregation Groups (VLAGs), the redundant uplinks remain active, utilizing all available bandwidth.

Two switches are paired into VLAG peers, and act as a single virtual entity for the purpose of establishing a multi-port trunk. Ports from both peers can be grouped into a VLAG and connected to the same LAG-capable target device. From the perspective of the target device, the ports connected to the VLAG peers appear to be a single trunk connecting to a single logical device. The target device uses the configured Tier ID to identify the VLAG peers as this single logical device. It is important that you use a unique Tier ID for each VLAG pair you configure. The VLAG-capable switches synchronize their logical view of the access layer port structure and internally prevent implicit loops. The VLAG topology also responds more quickly to link failure and does not result in unnecessary MAC flooding.

VLAGs are also useful in multi-layer environments for both uplink and downlink redundancy to any regular LAG-capable device. For example:

Figure 16. VLAG Application with Multiple Layers

Wherever ports from *both* peered switches are trunked to another device, the trunked ports must be configured as a VLAG. For example, VLAGs 1 and 3 must be configured for both VLAG Peer A switches. VLAGs 2 and 4 must be configured for both VLAG Peer B switches. VLAGs 3, 5, and 6 must be configured on both VLAG Peer C switches. Other devices connecting to the VLAG peers are configured using regular static or dynamic trunks.

Note: Do not configure a VLAG for connecting only one switch in the peer set to another device or peer set. For instance, in VLAG Peer C, a regular trunk is employed for the downlink connection to VLAG Peer B because only one of the VLAG Peer C switches is involved.

VLAG Capacities

Servers or switches that connect to the VLAG peers using a multi-port VLAG are considered VLAG clients. VLAG clients are not required to be VLAG-capable. The ports participating in the VLAG are configured as regular port trunks on the VLAG client end.

On the VLAG peers, the VLAGs are configured similarly to regular port trunks, using many of the same features and rules. See [“Ports and Trunking” on page 141](#) for general information concerning all port trunks.

Each VLAG begins as a regular port trunk on each VLAG-peer switch. The VLAG may be either a static trunk group (portchannel) or dynamic LACP trunk group, and consumes one slot from the overall port trunk capacity pool. The trunk type must match that used on VLAG client devices. Additional configuration is then required to implement the VLAG on both VLAG peer switches.

You may configure up to 64 trunk groups on the switch, with all types (regular or VLAG, static or LACP) sharing the same pool.

The maximum number of configurable VLAG instances is as follows:

- **With STP off:** Maximum of 31 VLAG instances
- **With STP on:**
 - **PVRST/MSTP with one VLAG instance per VLAN/STG:** Maximum of 31 VLAG instances
 - **PVRST/MSTP with one VLAG instance belonging to multiple VLANs/STGs:** Maximum of 20 VLAG instances

Each trunk type can contain up to 16 member ports, depending on the port type and availability.

VLAGs versus Port Trunks

Though similar to regular port trunks in many regards, VLAGs differ from regular port trunks in a number of important ways:

- A VLAG can consist of multiple ports on two VLAG peers, which are connected to one logical client device such as a server, switch, or another VLAG device.
- The participating ports on the client device are configured as a regular port trunk.
- The VLAG peers must be the same model, and run the same software version.
- VLAG peers require a dedicated inter-switch link (ISL) for synchronization. The ports used to create the ISL must have the following properties:
 - ISL ports must have VLAN tagging turned on.
 - ISL ports must be configured for all VLAG VLANs.
 - ISL ports must be placed into a regular port trunk group (dynamic or static).
 - A minimum of two ports on each switch are recommended for ISL use.
- Dynamic routing protocols, such as OSPF, cannot terminate on VLAGs.

- Routing over VLAGs is not supported. However, IP forwarding between subnets served by VLAGs can be accomplished using VRRP.
- VLAGs are configured using additional commands.
- It is recommended that end-devices connected to VLAG switches use NICs with dual-homing. This increases traffic efficiency, reduces ISL load, and provides faster link failover.

Configuring VLAGs

When configuring VLAG or making changes to your VLAG configuration, consider the following VLAG behavior:

- When adding a static Mrouter on VLAG links, ensure that you also add it on the ISL link to avoid VLAG link failure. If the VLAG link fails, traffic cannot be recovered through the ISL.
- When you enable VLAG on the switch, if an MSTP region mismatch is detected with the VLAG peer, a warning message appears alerting you of the mismatch so you can fix it.
- If you have enabled VLAG on the switch, and you need to change the STP mode, ensure that you first disable VLAG and then change the STP mode.
- When VLAG is enabled, you may see two root ports on the secondary VLAG switch. One of these will be the actual root port for the secondary VLAG switch and the other will be a root port synced with the primary VLAG switch.
- The LACP key used must be unique for each VLAG in the entire topology.
- The STG to VLAN mapping on both VLAG peers must be identical.

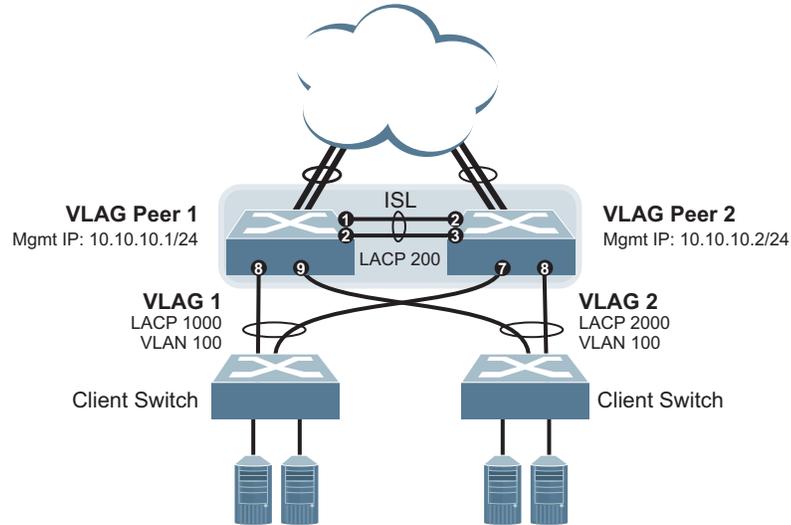

The following parameters must be identically configured on the VLAG ports of both the VLAG peers:

- VLANs
- Native VLAN tagging
- STP mode
- BPDU Guard setting
- STP port setting
- MAC aging timers
- Static MAC entries
- ACL configuration parameters
- QoS configuration parameters

Basic VLAG Configuration

Figure 18 shows an example configuration where two VLAG peers are used for aggregating traffic from downstream devices.

Figure 18. Basic VLAGs

In this example, each client switch is connected to both VLAG peers. On each client switch, the ports connecting to the VLAG peers are configured as a dynamic LACP port trunk. The VLAG peer switches share a dedicated ISL for synchronizing VLAG information. On the individual VLAG peers, each port leading to a specific client switch (and part of the client switch's port trunk) is configured as a VLAG.

In the following example configuration, only the configuration for VLAG 1 on VLAG Peer 1 is shown. VLAG Peer 2 and all other VLAGs are configured in a similar fashion.

Configure the ISL

The ISL connecting the VLAG peers is shared by all their VLAGs. The ISL needs to be configured only once on each VLAG peer.

1. Configure STP if required. Use PVRST or MSTP mode only:

```
RS 8264CS(config)# spanning-tree mode pvrst
```

2. Configure the ISL ports and place them into a port trunk group:

```
RS 8264CS(config)# interface port 1-2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# exit
RS 8264CS(config)# vlag isl adminkey 200
```

Notes:

- In this case, a dynamic trunk group is shown. A static trunk (portchannel) could be configured instead.
 - ISL ports and VLAG ports must be members of the same VLANs.
3. Configure VLAG Tier ID and enable VLAG globally. This is used to identify the VLAG switch in a multi-tier environment.

```
RS 8264CS(config)# vlag tier-id 10
```

4. Configure the ISL for the VLAG peer.

Make sure you configure the VLAG peer (VLAG Peer 2) using the same ISL trunk type (dynamic or static), the same VLAN, and the same STP mode and tier ID used on VLAG Peer 1.

Configure the VLAG

1. Configure the VLAN for VLAG 1. Make sure members include the ISL and VLAG 1 ports.

```
RS 8264CS(config)# vlan 100
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1-2,8
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

Note: In MSTP mode, VLANs are automatically mapped to CIST.

2. Place the VLAG 1 port(s) in a port trunk group:

```
RS 8264CS(config)# interface port 8
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 1000
RS 8264CS(config-if)# exit
```

3. Assign the trunk to the VLAG:

```
RS 8264CS(config)# vlag adminkey 1000 enable
```

4. Continue by configuring all required VLAGs on VLAG Peer 1, and then repeat the configuration for VLAG Peer 2.

For each corresponding VLAG on the peer, the port trunk type (dynamic or static), VLAN, and STP mode and ID must be the same as on VLAG Peer 1.

5. Enable VLAG globally:

```
RS 8264CS(config)# vlag enable
```

6. Verify the completed configuration:

```
RS 8264CS(config)# show vlag information
```

VLAG Configuration - VLANs Mapped to MSTI

Follow the steps below to configure VLAG in environments where the VLANs are mapped to Multiple Spanning Tree Instance (MSTI).

Configure the ISL

The ISL connecting the VLAG peers is shared by all their VLAGs. The ISL needs to be configured only once on each VLAG peer.

1. Configure STP:

```
RS 8264CS(config)# spanning-tree mode mst
```

2. Configure the ISL ports and place them into a port trunk group:

```
RS 8264CS(config)# interface port 1-2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# exit
RS 8264CS(config)# vlag isl adminkey 200
```

Notes:

- In this case, a dynamic trunk group is shown. A static trunk (portchannel) could be configured instead.
 - ISL ports and VLAG ports must be members of the same VLANs.
3. Configure VLAG Tier ID. This is used to identify the VLAG switch in a multi-tier environment.

```
RS 8264CS(config)# vlag tier-id 10
```

4. Configure the ISL for the VLAG peer.

Make sure you configure the VLAG peer (VLAG Peer 2) using the same ISL trunk type (dynamic or static), the same VLAN for VLAG ports and VLAG ISL ports, and the same STP mode and tier ID used on VLAG Peer 1.

Configure the VLAG

1. Configure the VLAN for VLAG 1.

```
RS 8264CS(config)# vlan 100
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 8
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

2. Map the VLAN to an MSTI.

```
RS 8264CS(config)# spanning-tree mst 1 vlan 100
RS 8264CS(config-mst)# instance 1 vlan 100
```

3. Place the VLAG 1 ports in a port trunk group (static or dynamic) and assign it to the VLAG:

```
RS 8264CS(config)# interface port 8
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 1000
RS 8264CS(config-if)# exit
RS 8264CS(config)# vlag adminkey 1000 enable
```

4. Enable VLAG.

```
RS 8264CS(config)# vlag enable
```

5. Continue by configuring all required VLAGs on VLAG Peer 1, then follow the steps for configuring VLAG Peer 2.

For each corresponding VLAG on the peer, the port trunk type (dynamic or static), the port's VLAN, STP mode, and ID must be the same as on VLAG Peer 1.

6. Enable VLAG.

```
RS 8264CS(config)# vlag enable
```

7. Verify the completed configuration:

```
RS 8264CS# show vlag
```

Configuring Health Check

We strongly recommend that you configure the G8264CS to check the health status of its VLAG peer. Although the operational status of the VLAG peer is generally determined via the ISL connection, configuring a network health check provides an alternate means to check peer status in case the ISL links fail. Use an independent link between the VLAG switches to configure health check.

Note: Configuring health check on an ISL VLAN interface or on a VLAG data port may impact the accuracy of the health check status.

1. Configure a management interface for the switch.

Note: If the switch does not have a dedicated management interface, configure a VLAN for the health check interface. The health check interface can be configured with an IPv4 address:

```
RS 8264CS(config)# interface ip 128
RS 8264CS(config-ip-if)# ip address 10.10.10.1 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

Note: Configure a similar interface on VLAG Peer 2. For example, use IP address 10.10.10.2.

2. Specify the IPv4 address of the VLAG Peer:

```
RS 8264CS(config)# vlag hlthchk peer-ip 10.10.10.2
```

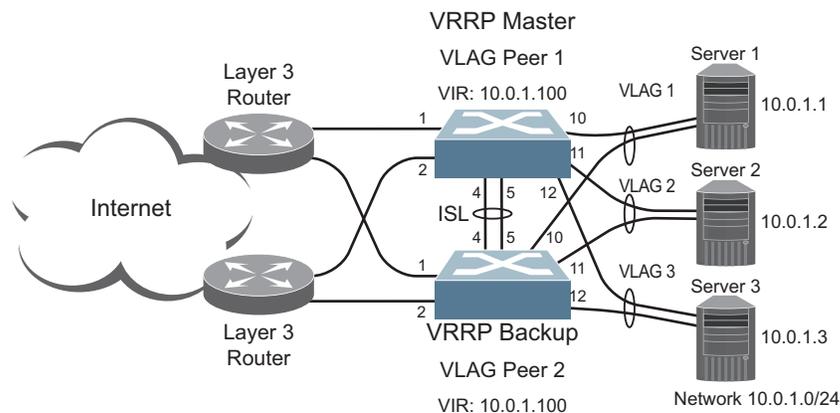

Note: For VLAG Peer 2, the management interface would be configured as 10.10.10.2, and the health check would be configured for 10.10.10.1, pointing back to VLAG Peer 1.

VLAGs with VRRP

Note: In a multi-layer environment, configure VRRP separately for each layer. We recommend that you configure VRRP only on the tier with uplinks. See [“Configuring VLAGs in Multiple Layers” on page 191](#).

VRRP (see [“Virtual Router Redundancy Protocol” on page 465](#)) can be used in conjunction with VLAGs and LACP-capable devices to provide seamless redundancy.

Figure 19. Active-Active Configuration using VRRP and VLAGs

Task 1: Configure VLAG Peer 1

Note: Before enabling VLAG, you must configure the VLAG tier ID and ISL portchannel.

1. Configure VLAG tier ID and enable VLAG globally.

```
RS 8264CS(config)# vlag tier-id 10
RS 8264CS(config)# vlag enable
```

2. Configure appropriate routing.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# enable
RS 8264CS(config-router-ospf)# exit
```

Although OSPF is used in this example, static routing could also be deployed. For more information, see [“OSPF” on page 409](#) or [“Basic IP Routing” on page 313](#).

3. Configure a server-facing interface.

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 10.0.1.10 255.255.255.0
RS 8264CS(config-ip-if)# vlan 100
RS 8264CS(config-ip-if)# exit
```

4. Turn on VRRP and configure the Virtual Interface Router.

```
RS 8264CS(config)# router vrrp
RS 8264CS(config-vrrp)# enable
RS 8264CS(config-vrrp)# virtual-router 1 virtual-router-id 1
RS 8264CS(config-vrrp)# virtual-router 1 interface 3
RS 8264CS(config-vrrp)# virtual-router 1 address 10.0.1.100
RS 8264CS(config-vrrp)# virtual-router 1 enable
```

5. Set the priority of Virtual Router 1 to 101, so that it becomes the Master.

```
RS 8264CS(config-vrrp)# virtual-router 1 priority 101
RS 8264CS(config-vrrp)# exit
```

6. Configure the ISL ports and place them into a port trunk group:

```
RS 8264CS(config)# interface port 4-5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 2000
RS 8264CS(config-if)# exit
```

Note: In this case, a dynamic trunk group is shown. A static trunk (portchannel) could be configured instead.

7. Configure the upstream ports.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport access vlan 10
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport access vlan 20
RS 8264CS(config-if)# exit
```

8. Configure the server ports.

```
RS 8264CS(config)# interface port 10
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 11
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 12
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
```

9. Configure all VLANs including VLANs for the VLAGs.

```
RS 8264CS(config)# vlan 10
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 10
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 20
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 20
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 100
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 4-5, 10-12
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 100
RS 8264CS(config-if)# exit
```

10. Configure Internet-facing interfaces.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 172.1.1.10 255.255.255.0
RS 8264CS(config-ip-if)# vlan 10
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 172.1.3.10 255.255.255.0
RS 8264CS(config-ip-if)# vlan 20
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

11. Place the VLAG port(s) in their port trunk groups.

```
RS 8264CS(config)# interface port 10
RS 8264CS(config-if)# lACP mode active
RS 8264CS(config-if)# lACP key 1000
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 11
RS 8264CS(config-if)# lACP mode active
RS 8264CS(config-if)# lACP key 1100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 12
RS 8264CS(config-if)# lACP mode active
RS 8264CS(config-if)# lACP key 1200
RS 8264CS(config-if)# exit
```

12. Assign the trunks to the VLAGs:

```
RS 8264CS(config)# vlag adminkey 1000 enable
RS 8264CS(config)# vlag adminkey 1100 enable
RS 8264CS(config)# vlag adminkey 1200 enable
```

13. Verify the completed configuration:

```
# show vlag
```

Task 2: Configure VLAG Peer 2

The VLAG peer (VLAG Peer 2) must be configured using the same ISL trunk type (dynamic or static), the same VLAN, and the same STP mode and Tier ID used on VLAG Switch 1.

For each corresponding VLAG on the peer, the port trunk type (dynamic or static), VLAN, and STP mode and ID must be the same as on VLAG Switch 1.

1. Configure VLAG tier ID and enable VLAG globally.

```
RS 8264CS(config)# vlag tier-id 10
RS 8264CS(config)# vlag enable
```

2. Configure appropriate routing.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# enable
RS 8264CS(config-router-ospf)# exit
```

Although OSPF is used in this example, static routing could also be deployed.

3. Configure a server-facing interface.

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 10.0.1.11 255.255.255.0
RS 8264CS(config-ip-if)# vlan 100
RS 8264CS(config-ip-if)# exit
```

4. Turn on VRRP and configure the Virtual Interface Router.

```
RS 8264CS(config)# router vrrp
RS 8264CS(config-vrrp)# enable
RS 8264CS(config-vrrp)# virtual-router 1 virtual-router-id 1
RS 8264CS(config-vrrp)# virtual-router 1 interface 3
RS 8264CS(config-vrrp)# virtual-router 1 address 10.0.1.100
RS 8264CS(config-vrrp)# virtual-router 1 enable
```

5. Configure the ISL ports and place them into a port trunk group:

```
RS 8264CS(config)# interface port 4-5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 2000
RS 8264CS(config-if)# exit
```

6. Configure the upstream ports.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport access vlan 30
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport access vlan 40
RS 8264CS(config-if)# exit
```

7. Configure the server ports.

```
RS 8264CS(config)# interface port 10
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 11
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 12
RS 8264CS(config-if)# switchport access vlan 100
RS 8264CS(config-if)# exit
```

8. Configure all VLANs including VLANs for the VLAGs.

```
RS 8264CS(config)# vlan 30
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 30
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 40
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 40
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 100
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 4-5,10-12
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 100
RS 8264CS(config-if)# exit
```

9. Configure Internet-facing interfaces.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 172.1.2.11 255.255.255.0
RS 8264CS(config-ip-if)# vlan 30
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 172.1.4.12 255.255.255.0
RS 8264CS(config-ip-if)# vlan 40
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

10. Place the VLAG port(s) in their port trunk groups.

```
RS 8264CS(config)# interface port 10
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 1000
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 11
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 1100
RS 8264CS(config-if)# exit
RS 8264CS(config)# interface port 12
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# lacp key 1200
RS 8264CS(config-if)# exit
```

11. Assign the trunks to the VLAGs:

```
RS 8264CS(config)# vlag adminkey 1000 enable
RS 8264CS(config)# vlag adminkey 1100 enable
RS 8264CS(config)# vlag adminkey 1200 enable
```

12. Verify the completed configuration:

```
# show vlag
```

Configuring VLAGs in Multiple Layers

Figure 20. VLAG in Multiple Layers

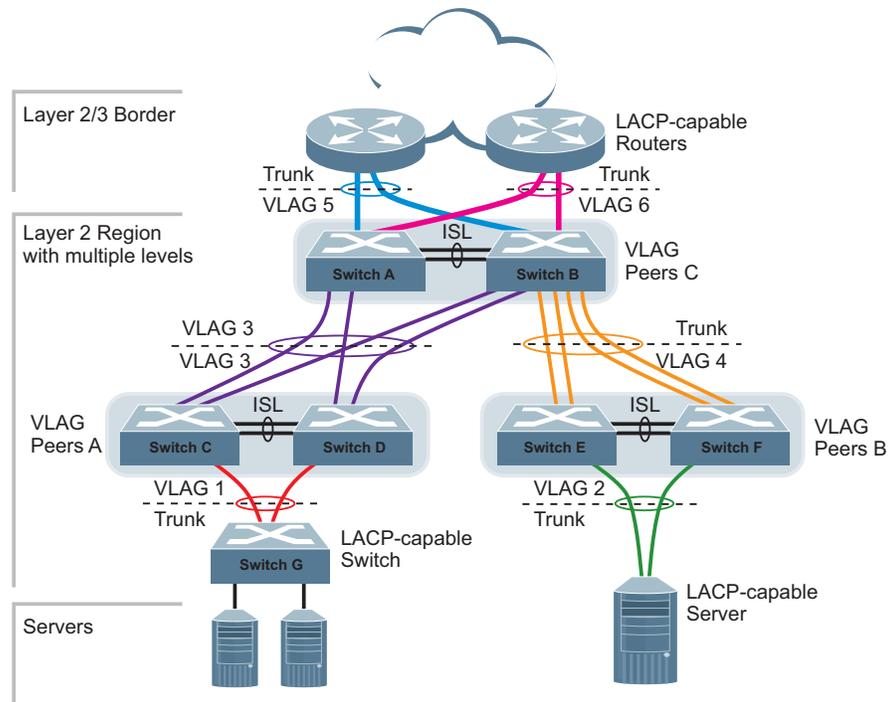

Figure 20 shows an example of VLAG being used in a multi-layer environment. Following are the configuration steps for the topology.

Task 1: Configure Layer 2/3 border switches.

Configure ports on border switch as follows:

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 100
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

Repeat these commands for the second border switch.

Task 2: Configure switches in the Layer 2 region.

Consider the following:

- ISL ports on switches A and B - ports 1, 2
- Ports connecting to Layer 2/3 - ports 5, 6
- Ports on switches A and B connecting to switches C and D: ports 10, 11
- Ports on switch B connecting to switch E: ports 15, 16
- Ports on switch B connecting to switch F: ports 17, 18

1. Configure VLAG tier ID and enable VLAG globally.

```
RS 8264CS(config)# vlag tier-id 10
RS 8264CS(config)# vlag enable
```

2. Configure ISL ports on Switch A.

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlag isl adminkey 200
RS 8264CS(config-vlan)# exit
```

3. Configure port on Switch A connecting to Layer 2/3 router 1.

```
RS 8264CS(config)# vlan 10
VLAN number 10 with name "VLAN 10" created
VLAN 10 was assigned to STG 10
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1,2,5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 10
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 5
RS 8264CS(config-if)# lacp key 400
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlag adminkey 400 enable
```

Repeat these steps on Switch B for ports connecting to Layer 2/3 router 1.

4. Configure port on Switch A connecting to Layer 2/3 router 2.

```
RS 8264CS(config)# vlan 20
VLAN number 20 with name "VLAN 20" created
VLAN 20 was assigned to STG 20
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1,2,6
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 20
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 6
RS 8264CS(config-if)# lacp key 500
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlag adminkey 500 enable
```

Repeat these commands on Switch B for ports connecting to Layer 2/3 router 2.

5. Configure ports on Switch A connecting to downstream VLAG switches C and D.

```
RS 8264CS(config)# vlan 20
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 10,11
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 20
RS 8264CS(config-if)# lacp key 600
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlag adminkey 600 enable
```

Repeat these commands on Switch B for ports connecting to downstream VLAG switch C and D.

6. Configure ports on Switch B connecting to downstream switches E and F.

```
RS 8264CS(config)# vlan 30
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 15-18
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 30
RS 8264CS(config-if)# lacp key 700
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

7. Configure ISL between switches C and D, and between E and F as shown in Step 1.
8. Configure the Switch G as shown in Step 2.

Traffic Forwarding

In a VLAG with PIM topology, traffic forwarded by the upstream router is managed as follows:

- If the primary and secondary VLAG ports are up, the primary switch forwards traffic to the receiver. The secondary switch blocks the traffic. Multicast entries are created on both the VLAG switches: primary VLAG switch with forward state; secondary VLAG switch with pruned state.
- If the primary VLAG port fails, the secondary VLAG switch forwards traffic to the receiver. Multicast entries are created on both the VLAG switches: primary VLAG switch with forward state; secondary VLAG switch with VLAG pruned state.
- If the secondary VLAG port fails, the primary VLAG switch forwards traffic to the receiver. Multicast entries are created on both the VLAG switches: primary VLAG switch with forward state; secondary VLAG switch with pruned state.
- If the primary VLAG switch is down, the secondary VLAG switch forwards traffic to the receiver. When the primary VLAG switch boots up again, it becomes the secondary VLAG switch and blocks traffic to the receiver. The VLAG switch that was secondary initially becomes the primary and continues forwarding traffic to the receiver.

- If the secondary VLAG switch is down, the primary VLAG switch forwards traffic to the receiver. When the secondary VLAG switch is up, it blocks traffic. The primary switch forwards traffic to the receiver.
- If the uplink to the primary VLAG switch is down, the secondary VLAG switch forwards traffic to the receiver and to the primary VLAG switch over the ISL. The primary VLAG switch blocks traffic to the receiver so the receiver does not get double traffic. Both the VLAG switches will have multicast entries in forward state.
- If the uplink to the secondary VLAG switch is down, the primary VLAG switch forwards traffic to the receiver and to the secondary VLAG switch over the ISL. The secondary VLAG switch blocks traffic to the receiver so the receiver does not get double traffic. Both the VLAG switches will have multicast entries in the forward state.

Health Check

In a VLAG with PIM topology, you must configure health check. See [“Configuring Health Check” on page 184](#).

When health check is configured, and the ISL is down, the primary VLAG switch forwards traffic to the receiver. The secondary VLAG switch ports will be errdisable state and will block traffic to the receiver.

Chapter 13. Quality of Service

Quality of Service features allow you to allocate network resources to mission-critical applications at the expense of applications that are less sensitive to such factors as time delays or network congestion. You can configure your network to prioritize specific types of traffic, ensuring that each type receives the appropriate Quality of Service (QoS) level.

The following topics are discussed in this section:

- [“QoS Overview” on page 196](#)
- [“Using ACL Filters” on page 197](#)
- [“Using DSCP Values to Provide QoS” on page 199](#)
- [“Using 802.1p Priority to Provide QoS” on page 205](#)
- [“Queuing and Scheduling” on page 206](#)
- [“Control Plane Protection” on page 206](#)
- [“WRED with ECN” on page 207](#)

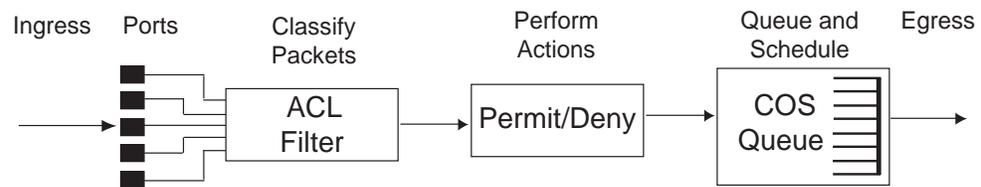

QoS Overview

QoS helps you allocate guaranteed bandwidth to the critical applications, and limit bandwidth for less critical applications. Applications such as video and voice must have a certain amount of bandwidth to work correctly; using QoS, you can provide that bandwidth when necessary. Also, you can put a high priority on applications that are sensitive to timing out or that cannot tolerate delay, by assigning their traffic to a high-priority queue.

By assigning QoS levels to traffic flows on your network, you can ensure that network resources are allocated where they are needed most. QoS features allow you to prioritize network traffic, thereby providing better service for selected applications.

Figure 21 shows the basic QoS model used by the switch.

Figure 21. QoS Model

The basic QoS model works as follows:

- Classify traffic:
 - Read DSCP value.
 - Read 802.1p priority value.
 - Match ACL filter parameters.
- Perform actions:
 - Define bandwidth and burst parameters
 - Select actions to perform on in-profile and out-of-profile traffic
 - Deny packets
 - Permit packets
 - Mark DSCP or 802.1p Priority
 - Set COS queue (with or without re-marking)
- Queue and schedule traffic:
 - Place packets in one of the COS queues.
 - Schedule transmission based on the COS queue.

Using ACL Filters

Access Control Lists (ACLs) are filters that allow you to classify and segment traffic, so you can provide different levels of service to different traffic types. Each filter defines the conditions that must match for inclusion in the filter, and also the actions that are performed when a match is made.

Lenovo Networking OS 8.2 supports up to 256 ACLs.

The G8264CS allows you to classify packets based on various parameters. For example:

- Ethernet: source MAC, destination MAC, VLAN number/mask, Ethernet type, priority.
- IPv4: Source IP address/mask, destination address/mask, type of service, IP protocol number.
- TCP/UDP: Source port, destination port, TCP flag.
- Packet format

For ACL details, see [“Access Control Lists” on page 105](#).

Summary of ACL Actions

Actions determine how the traffic is treated. The G8264CS QoS actions include the following:

- Pass or Drop
- Re-mark a new DiffServ Code Point (DSCP)
- Re-mark the 802.1p field
- Set the COS queue

ACL Metering and Re-Marking

You can define a profile for the aggregate traffic flowing through the G8264CS by configuring a QoS meter (if desired) and assigning ACLs to ports. When you add ACLs to a port, make sure they are ordered correctly in terms of precedence.

Actions taken by an ACL are called *In-Profile* actions. You can configure additional In-Profile and Out-of-Profile actions on a port. Data traffic can be metered, and re-marked to ensure that the traffic flow provides certain levels of service in terms of bandwidth for different types of network traffic.

Metering

QoS metering provides different levels of service to data streams through user-configurable parameters. A meter is used to measure the traffic stream against a traffic profile, which you create. Thus, creating meters yields In-Profile and Out-of-Profile traffic for each ACL, as follows:

- **In-Profile**—If there is no meter configured or if the packet conforms to the meter, the packet is classified as In-Profile.
- **Out-of-Profile**—If a meter is configured and the packet does not conform to the meter (exceeds the committed rate or maximum burst rate of the meter), the packet is classified as Out-of-Profile.

Using meters, you set a Committed Rate in Kbps (multiples of 64 Mbps). All traffic within this Committed Rate is In-Profile. Additionally, you set a Maximum Burst Size that specifies an allowed data burst larger than the Committed Rate for a brief period. These parameters define the In-Profile traffic.

Meters keep the sorted packets within certain parameters. You can configure a meter on an ACL, and perform actions on metered traffic, such as packet re-marking.

Re-Marking

Re-marking allows for the treatment of packets to be reset based on new network specifications or desired levels of service. You can configure the ACL to re-mark a packet as follows:

- Change the DSCP value of a packet, used to specify the service level traffic receives.
- Change the 802.1p priority of a packet.

Using DSCP Values to Provide QoS

The switch uses the Differentiated Services (DiffServ) architecture to provide QoS functions. DiffServ is described in IETF RFCs 2474 and 2475.

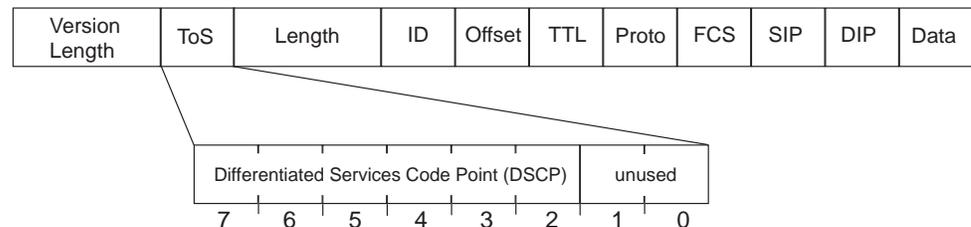

The six most significant bits in the TOS byte of the IP header are defined as DiffServ Code Points (DSCP). Packets are marked with a certain value depending on the type of treatment the packet must receive in the network device. DSCP is a measure of the Quality of Service (QoS) level of the packet.

The switch can classify traffic by reading the DiffServ Code Point (DSCP) or IEEE 802.1p priority value, or by using filters to match specific criteria. When network traffic attributes match those specified in a traffic pattern, the policy instructs the switch to perform specified actions on each packet that passes through it. The packets are assigned to different Class of Service (COS) queues and scheduled for transmission.

Differentiated Services Concepts

To differentiate between traffic flows, packets can be classified by their DSCP value. The Differentiated Services (DS) field in the IP header is an octet, and the first six bits, called the DS Code Point (DSCP), can provide QoS functions. Each packet carries its own QoS state in the DSCP. There are 64 possible DSCP values (0-63).

Figure 22. Layer 3 IPv4 packet

The switch can perform the following actions to the DSCP:

- Read the DSCP value of ingress packets.
- Re-mark the DSCP value to a new value
- Map the DSCP value to a Class of Service queue (COSq).

The switch can use the DSCP value to direct traffic prioritization.

With DiffServ, you can establish policies to direct traffic. A policy is a traffic-controlling mechanism that monitors the characteristics of the traffic, (for example, its source, destination, and protocol) and performs a controlling action on the traffic when certain characteristics are matched.

Trusted/Untrusted Ports

By default, all ports on the G8264CS are trusted. To configure untrusted ports, re-mark the DSCP value of the incoming packet to a lower DSCP value using the following commands:

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# dscp-marking
RS 8264CS(config-if)# exit
RS 8264CS(config)# qos dscp dscp-mapping <DSCP value (0-63)> <new value>
RS 8264CS(config)# qos dscp re-marking
```

Per Hop Behavior

The DSCP value determines the Per Hop Behavior (PHB) of each packet. The PHB is the forwarding treatment given to packets at each hop. QoS policies are built by applying a set of rules to packets, based on the DSCP value, as they hop through the network.

The default settings are based on the following standard PHBs, as defined in the IEEE standards:

- Expedited Forwarding (EF)—This PHB has the highest egress priority and lowest drop precedence level. EF traffic is forwarded ahead of all other traffic. EF PHB is described in RFC 2598.
- Assured Forwarding (AF)—This PHB contains four service levels, each with a different drop precedence, as shown in the following table. Routers use drop precedence to determine which packets to discard last when the network becomes congested. AF PHB is described in RFC 2597.

Drop Precedence	Class 1	Class 2	Class 3	Class 4
Low	AF11 (DSCP 10)	AF21 (DSCP 18)	AF31 (DSCP 26)	AF41 (DSCP 34)
Medium	AF12 (DSCP 12)	AF22 (DSCP 20)	AF32 (DSCP 28)	AF42 (DSCP 36)
High	AF13 (DSCP 14)	AF23 (DSCP 22)	AF33 (DSCP 30)	AF43 (DSCP 38)

- Class Selector (CS)—This PHB has eight priority classes, with CS7 representing the highest priority, and CS0 representing the lowest priority, as shown in the following table. CS PHB is described in RFC 2474.

Priority	Class Selector	DSCP
Highest	CS7	56
	CS6	48
	CS5	40
	CS4	32
	CS3	24
	CS2	16
	CS1	8
Lowest	CS0	0

QoS Levels

Table 19 shows the default service levels provided by the switch, listed from highest to lowest importance:

Table 19. *Default QoS Service Levels*

Service Level	Default PHB	802.1p Priority
Critical	CS7	7
Network Control	CS6	6
Premium	EF, CS5	5
Platinum	AF41, AF42, AF43, CS4	4
Gold	AF31, AF32, AF33, CS3	3
Silver	AF21, AF22, AF23, CS2	2
Bronze	AF11, AF12, AF13, CS1	1
Standard	DF, CS0	0

DSCP Re-Marking and Mapping

The switch can use the DSCP value of ingress packets to re-mark the DSCP to a new value, and to set an 802.1p priority value. Use the following command to view the default settings.

```
RS 8264CS# show qos dscp
Current DSCP Remarking Configuration: OFF
```

DSCP	New DSCP	New 802.1p Prio
0	0	0
1	1	0
2	2	0
3	3	0
4	4	0
5	5	0
6	6	0
7	7	0
8	8	1
9	9	0
10	10	1
...		
54	54	0
55	55	0
56	56	7
57	57	0
58	58	0
59	59	0
60	60	0
61	61	0
62	62	0
63	63	0

Use the following command to turn on DSCP re-marking globally:

```
RS 8264CS(config)# qos dscp re-marking
```

Then you must enable DSCP re-marking on any port that you wish to perform this function (Interface Port mode).

Note: If an ACL meter is configured for DSCP re-marking, the meter function takes precedence over QoS re-marking.

DSCP Re-Marking Configuration Examples

Example 1

The following example includes the basic steps for re-marking DSCP value and mapping DSCP value to 802.1p.

1. Turn DSCP re-marking on globally, and define the DSCP-DSCP-802.1p mapping. You can use the default mapping.

```
RS 8264CS(config)# qos dscp re-marking
RS 8264CS(config)# qos dscp dscp-mapping <DSCP value (0-63)> <new value>
RS 8264CS(config)# qos dscp dot1p-mapping <DSCP value (0-63)> <802.1p value>
```

2. Enable DSCP re-marking on a port.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# qos dscp re-marking
RS 8264CS(config-if)# exit
```

Example 2

The following example assigns strict priority to VoIP traffic and a lower priority to all other traffic.

1. Create an ACL to re-mark DSCP value and COS queue for all VoIP packets.

```
RS 8264CS(config)# access-control list 2 tcp-udp source-port 5060 0xffff
RS 8264CS(config)# access-control list 2 meter committed-rate 10000000
RS 8264CS(config)# access-control list 2 meter enable
RS 8264CS(config)# access-control list 2 re-mark in-profile dscp 56
RS 8264CS(config)# access-control list 2 re-mark dot1p 7
RS 8264CS(config)# access-control list 2 action permit
```

2. Create an ACL to set a low priority to all other traffic.

```
RS 8264CS(config)# access-control list 3 action set-priority 1
RS 8264CS(config)# access-control list 3 action permit
```

3. Apply the ACLs to a port and enable DSCP marking.

```
RS 8264CS(config)# interface port 5
RS 8264CS(config-if)# access-control list 2
RS 8264CS(config-if)# access-control list 3 ethernet source-mac-address
00:00:00:00:00:00 00:00:00:00:00:00
RS 8264CS(config-if)# dscp-marking
RS 8264CS(config-if)# exit
```

4. Enable DSCP re-marking globally.

```
RS 8264CS(config)# qos dscp re-marking
```

5. Assign the DSCP re-mark value.

```
RS 8264CS(config)# qos dscp dscp-mapping 40 9
RS 8264CS(config)# qos dscp dscp-mapping 46 9
```

6. Assign strict priority to VoIP COS queue.

```
RS 8264CS(config)# qos transmit-queue weight-cos 7 0
```

7. Map priority value to COS queue for non-VoIP traffic.

```
RS 8264CS(config)# qos transmit-queue mapping 1 1
```

8. Assign weight to the non-VoIP COS queue.

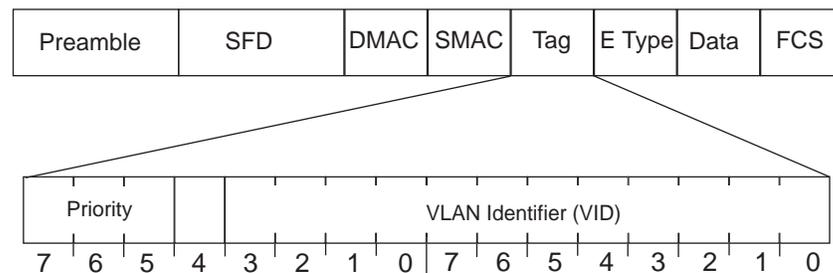

```
RS 8264CS(config)# qos transmit-queue weight-cos 1 2
```

Using 802.1p Priority to Provide QoS

The G8264CS provides Quality of Service functions based on the priority bits in a packet's VLAN header. (The priority bits are defined by the 802.1p standard within the IEEE 802.1Q VLAN header.) The 802.1p bits, if present in the packet, specify the priority to be given to packets during forwarding. Packets with a numerically higher (non-zero) priority are given forwarding preference over packets with lower priority value.

The IEEE 802.1p standard uses eight levels of priority (0-7). Priority 7 is assigned to highest priority network traffic, such as OSPF or RIP routing table updates, priorities 5-6 are assigned to delay-sensitive applications such as voice and video, and lower priorities are assigned to standard applications. A value of 0 (zero) indicates a "best effort" traffic prioritization, and this is the default when traffic priority has not been configured on your network. The switch can filter packets based on the 802.1p values.

Figure 23. Layer 2 802.1q/802.1p VLAN tagged packet

Ingress packets receive a priority value, as follows:

- **Tagged packets**—switch reads the 802.1p priority in the VLAN tag.
- **Untagged packets**—switch tags the packet and assigns an 802.1p priority value, based on the port's default 802.1p priority.

Egress packets are placed in a COS queue based on the priority value, and scheduled for transmission based on the COS queue number. Higher COS queue numbers provide forwarding precedence.

To configure a port's default 802.1p priority value, use the following commands.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# dot1p <802.1p value (0-7)>
RS 8264CS(config-if)# exit
```

Queuing and Scheduling

The G8264CS can be configured to have 8 output Class of Service (COS) queues per port, into which each packet is placed. Each packet's 802.1p priority determines its COS queue, except when an ACL action sets the COS queue of the packet.

Note: When vNIC operations are enabled, the total number of COS queues available is 4.

You can configure the following attributes for COS queues:

- Map 802.1p priority value to a COS queue
- Define the scheduling weight of each COS queue

You can map 802.1p priority value to a COS queue, as follows:

```
RS 8264CS(config)# qos transmit-queue mapping <802.1p priority value (0-7)>
<COS queue (0-7)>
```

To set the COS queue scheduling weight, use the following command.

```
RS 8264CS(config)# qos transmit-queue weight-cos <COSq number>
<COSq weight (0-15)>
```

Control Plane Protection

Control plane receives packets that are required for the internal protocol state machines. This type of traffic is usually received at low rate. However, in some situations such as DOS attacks, the switch may receive this traffic at a high rate. If the control plane protocols are unable to process the high rate of traffic, the switch may become unstable.

The control plane receives packets that are channeled through protocol-specific packet queues. Multiple protocols can be channeled through a common packet queue. However, one protocol cannot be channeled through multiple packet queues. These packet queues are applicable only to the packets received by the software and does not impact the regular switching or routing traffic. Packet queue with a higher number has higher priority.

You can configure the bandwidth for each packet queue. Protocols that share a packet queue will also share the bandwidth.

The following commands configure the control plane protection (CoPP) feature:

```
RS 8264CS(config)# qos protocol-packet-control packet-queue-map <0-47>
<protocol> (Configure a queue for a protocol)
RS 8264CS(config)# qos protocol-packet-control rate-limit-packet-queue
<0-47> <1-10000> (Set the bandwidth for the queue,
in packets per second)
```

WRED with ECN

Weighted Random Early Detection (WRED) is a congestion avoidance algorithm that helps prevent a TCP collapse, where a congested port indiscriminately drops packets from all sessions. The transmitting hosts wait to retransmit resulting in a dramatic drop in throughput. Often times, this TCP collapse repeats in a cycle, which results in a saw-tooth pattern of throughput. WRED selectively drops packets before the queue gets full, allowing majority of the traffic to flow smoothly.

WRED discards packets based on the CoS queues. Packets marked with lower priorities are discarded first.

Explicit Congestion Notification (ECN) is an extension to WRED. For packets that are ECN-aware, the ECN bit is marked to signal impending congestion instead of dropping packets. The transmitting hosts then slow down sending packets.

How WRED/ECN work together

For implementing WRED, you must define a profile with minimum threshold, maximum threshold, and a maximum drop probability. The profiles can be defined on a port or a CoS.

For implementing ECN, you require ECN-specific field that has two bits—the ECN-capable Transport (ECT) bit and the CE (Congestion Experienced) bit—in the IP header. ECN is identified and defined by the values in these bits in the Differentiated Services field of IP Header. [Table 20](#) shows the combination values of the ECN bits.

Table 20. *ECN Bit Setting*

ECT Bit	CE Bit	Description
0	0	Not ECN-capable
0	1	Endpoints of the transport protocol are ECN-capable
1	0	Endpoints of the transport protocol are ECN-capable
1	1	Congestion experienced

WRED and ECN work together as follows:

- If the number of packets in the queue is less than the minimum threshold, packets are transmitted. This happens irrespective of the ECN bit setting, and on networks where only WRED (without ECN) is enabled.
- If the number of packets in the queue is between the minimum threshold and the maximum threshold, one of the following occurs:
 - If the ECN field on the packet indicates that the endpoints are ECN-capable and the WRED algorithm determines that the packet has likely been dropped based on the drop probability, the ECT and CE bits for the packet are changed to 1, and the packet is transmitted.
 - If the ECN field on the packet indicates that neither endpoint is ECN-capable, the packet may be dropped based on the WRED drop probability. This is true even in cases where only WRED (without ECN) is enabled.
 - If the ECN field on the packet indicates that the network is experiencing congestion, the packet is transmitted. No further marking is required.
- If the number of packets in the queue is greater than the maximum threshold, packets are dropped based on the drop probability. This is the identical treatment a packet receives when only WRED (without ECN) is enabled.

Configuring WRED/ECN

For configuring WRED, you must define a TCP profile and a non-TCP profile. WRED prioritizes TCP traffic over non-TCP traffic.

For configuring ECN, you must define a TCP profile. You don't need a non-TCP profile as ECN can be enabled only for TCP traffic.

If you do not configure the profiles, the profile thresholds are set to maximum value of 0xFFFF to avoid drops.

Note: WRED/ECN can be configured only on physical ports and not on trunks. WRED and ECN are applicable only to unicast traffic.

Consider the following guidelines for configuring WRED/ECN:

- Profiles can be configured globally or per port. Global profiles are applicable to all ports.
- Always enable the global profile before applying the port-level profile.

Note: You can enable the global profile and disable the port-level profile. However, you must not enable the port-level profile if the global profile is disabled.

- WRED settings are dependent on Memory Management Unit (MMU) Settings. If you change the MMU setting, it could impact WRED functionality.
- You cannot enable WRED if you have QoS buffer settings such as Converged Enhanced Ethernet (CEE), Priority-based Flow Control (PFC), or Enhanced Transmission Selection (ETS).
- The number of WRED profiles per-port must match the total number of COS Queues configured in the system.
- If you have configured a TCP profile and enabled ECN, ECN remarking happens only if all traffic experiencing congestion is TCP traffic.
- Configure a TCP profile only after enabling ECN on the interface.

- You can apply TCP and non-TCP profile configurations irrespective of ECN status (enabled/disabled).

WRED/ECN Configuration Example

Follow these steps to enable WRED/ECN and configure a global and/or port-level profile. If you configure global and port-level profile, WRED/ECN uses the port-level profile to make transmit/drop decisions when experiencing traffic congestion.

Configure Global Profile for WRED

1. Enable WRED globally.

```
RS 8264CS(config)# qos random-detect enable
```

2. Enable a transmit queue.

```
RS 8264CS(config)# qos random-detect transmit-queue 0 enable
```

3. Configure WRED thresholds (minimum, maximum, and drop rate) for TCP traffic.

```
RS 8264CS(config)# qos random-detect transmit-queue 0 tcp min-threshold 1  
max-threshold 2 drop-rate 3
```

Note: Percentages are of Average Queue available in hardware and not percentages of traffic.

4. Configure WRED thresholds (minimum, maximum, and drop rate) for non-TCP traffic.

```
RS 8264CS(config)# qos random-detect transmit-queue 0 non-tcp  
min-threshold 4 max-threshold 5 drop-rate 6
```

5. Select the port.

```
RS 8264CS(config)# interface port 1
```

6. Enable WRED for the port.

```
RS 8264CS(config-if)# random-detect enable  
RS 8264CS(config-if)# exit
```

Configure Port-level Profile for WRED

1. Enable WRED globally.

```
RS 8264CS(config)# qos random-detect enable
```

2. Select the port.

```
RS 8264CS(config)# interface port 1
```

3. Enable WRED for the port .

```
RS 8264CS(config-if)# random-detect enable
```

4. Enable a transmit queue.

```
RS 8264CS(config-if)# random-detect transmit-queue 0 enable
```

5. Configure WRED thresholds (minimum, maximum, and drop rate) for TCP traffic.

```
RS 8264CS(config-if)# random-detect transmit-queue 0 tcp min-threshold 11  
max-threshold 22 drop-rate 33
```

Note: Percentages are of Average Queue available in hardware and not percentages of traffic.

6. Configure WRED thresholds (minimum, maximum, and drop rate) for non-TCP traffic.

```
RS 8264CS(config-if)# random-detect transmit-queue 0 non-tcp  
min-threshold 44 max-threshold 55 drop-rate 66  
RS 8264CS(config-if)# exit
```

Configure Global Profile for ECN

1. Enable ECN globally.

```
RS 8264CS(config)# qos random-detect ecn enable
```

2. Enable a transmit queue.

```
RS 8264CS(config)# qos random-detect transmit-queue 0 enable
```

3. Configure ECN thresholds (minimum, maximum, and drop rate) for TCP traffic.

```
RS 8264CS(config)# qos random-detect transmit-queue 0 tcp min-threshold 1  
max-threshold 2 drop-rate 3
```

Note: Percentages are of Average Queue available in hardware and not percentages of traffic.

4. Select the port.

```
RS 8264CS(config)# interface port 1
```

5. Enable ECN for the port.

```
RS 8264CS(config-if)# random-detect ecn enable  
RS 8264CS(config-if)# exit
```

Configure Port-level Profile for ECN

1. Enable ECN globally.

```
RS 8264CS(config)# qos random-detect ecn enable
```

2. Select the port.

```
RS 8264CS(config)# interface port 1
```

3. Enable ECN for the port.

```
RS 8264CS(config-if)# random-detect ecn enable
```

4. Enable a transmit queue.

```
RS 8264CS(config-if)# random-detect transmit-queue 0 enable
```

5. Configure ECN thresholds (minimum, maximum, and drop rate) for TCP traffic.

```
RS 8264CS(config-if)# random-detect transmit-queue 0 tcp min-threshold 11  
max-threshold 22 drop-rate 33  
RS 8264CS(config-if)# exit
```

Note: Percentages are of Average Queue available in hardware and not percentages of traffic.

Verifying WRED/ECN

Use the following command to view global WRED/ECN information.

```
RS 8264CS(config)# show qos random-detect

Part 4: Advanced Switching Features

Chapter 14. Virtualization

Virtualization allows resources to be allocated in a fluid manner based on the logical needs of the data center, rather than on the strict, physical nature of components. The following virtualization features are included in Lenovo Networking OS 8.2 on the RackSwitch G8264CS (G8264CS):

- Virtual Local Area Networks (VLANs)

VLANs are commonly used to split groups of networks into manageable broadcast domains, create logical segmentation of workgroups, and to enforce security policies among logical network segments.

For details on this feature, see [“VLANs” on page 123](#).

- Port trunking

A port trunk pools multiple physical switch ports into a single, high-bandwidth logical link to other devices. In addition to aggregating capacity, trunks provides link redundancy.

For details on this feature, see [“Ports and Trunking” on page 141](#).

- Virtual Link Aggregation (VLAs)

With VLAs, two switches can act as a single logical device for the purpose of establishing port trunking. Active trunk links from one device can lead to both VLA peer switches, providing enhanced redundancy, including active-active VRRP configuration.

For details on this feature, see [“Virtual Link Aggregation Groups” on page 175](#)

- Virtual Network Interface Card (vNIC) support

Some NICs, such as the Emulex Virtual Fabric Adapter, can virtualize NIC resources, presenting multiple virtual NICs to the server’s OS or hypervisor. Each vNIC appears as a regular, independent NIC with some portion of the physical NIC’s overall bandwidth. Lenovo N/OS 8.2 supports up to four vNICs over each server-side switch port.

For details on this feature, see [“Virtual NICs” on page 217](#).

- VMready

The switch’s VMready software makes it *virtualization aware*. Servers that run hypervisor software with multiple instances of one or more operating systems can present each as an independent *virtual machine* (VM). With VMready, the switch automatically discovers virtual machines (VMs) connected to switch.

For details on this feature, see [“VMready” on page 227](#).

- Edge Virtual Bridging

Edge Virtual Bridging (EVB) allows networks to become virtual machine (VM)-aware. EVB bridges the gap between physical and virtual network resources. In EVB environments, physical end stations, containing multiple virtual end stations, use a bridge to form a LAN. The virtual NIC (vNIC) configuration information of a virtual machine is available to these EVB devices.

For details on this feature, see [“Edge Virtual Bridging” on page 301](#).

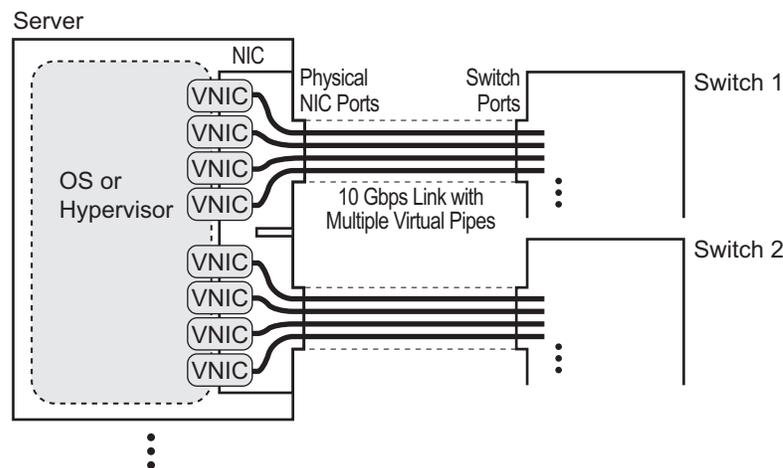

N/OS virtualization features provide a highly-flexible framework for allocating and managing switch resources.

Chapter 15. Virtual NICs

A Network Interface Controller (NIC) is a component within a server that allows the server to be connected to a network. The NIC provides the physical point of connection, as well as internal software for encoding and decoding network packets.

Virtualizing the NIC helps to resolve issues caused by limited NIC slot availability. By virtualizing a 10Gbps NIC, its resources can be divided into multiple logical instances known as virtual NICs (vNICs). Each vNIC appears as a regular, independent NIC to the server operating system or a hypervisor, with each vNIC using some portion of the physical NIC's overall bandwidth.

Figure 24. Virtualizing the NIC for Multiple Virtual Pipes on Each Link

A G8264CS with Lenovo Networking OS 8.2 supports the Emulex Virtual Fabric Adapter (VFA) to provide the following vNIC features:

- Up to four vNICs are supported on each server port.
- vNICs can be grouped together, along with regular server ports, uplink ports, or trunk groups, to define vNIC groups for enforcing communication boundaries.
- In the case of a failure on the uplink ports associated with a vNIC group, the switch can signal affected vNICs for failover while permitting other vNICs to continue operation.
- Each vNIC can be independently allocated a symmetric percentage of the 10Gbps bandwidth on the link (from NIC to switch, and from switch to NIC).
- The G8264CS can be used as the single point of vNIC configuration as long as the Emulex NIC is working in Lenovo Virtual Fabric mode.

The following restrictions apply to vNICs:

- vNICs are not supported simultaneously with VM groups (see [“VMready” on page 227](#)) on the same switch ports.

By default, vNICs are disabled. As described in the following sections, the administrator must first define server ports prior to configuring and enabling vNICs as discussed in the rest of this section.

Defining Server Ports

vNICs are supported only on ports connected to servers. Before you configure vNICs on a port, the port must first be defined as a server port using the following command:

```
RS 8264CS(config)# system server-ports port <port alias or number>
```

Ports that are not defined as server ports are considered uplink ports and do not support vNICs.

Enabling the vNIC Feature

The vNIC feature can be globally enabled using the following command:

```
RS 8264CS(config)# vnic enable
```

vNIC IDs

vNIC IDs on the Switch

Lenovo N/OS 8.2 supports up to four vNICs attached to each server port. Each vNIC is provided its own independent virtual pipe on the port.

On the switch, each vNIC is identified by its port and vNIC number as follows:

<port number or alias>. <vNIC pipe number (1-4)>

For example:

1.1, 1.2, 1.3, and 1.4 represent the vNICs on port 1.

2.1, 2.2, 2.3, and 2.4 represent the vNICs on port 2, etc.

These vNIC IDs are used when adding vNICs to vNIC groups, and are shown in some configuration and information displays.

vNIC Interface Names on the Server

When running in virtualization mode, the Emulex Virtual Fabric Adapter presents eight vNICs to the OS or hypervisor (four for each of the two physical NIC ports). Each vNIC is identified in the OS or hypervisor with a different vNIC function number (0-7). vNIC function numbers correlate to vNIC IDs on the switch as follows:

Table 21. vNIC ID Correlation

PCIe Function ID	NIC Port	vNIC Pipe	vNIC ID
0	0	1	x.1
2	0	2	x.2

Table 21. *vNIC ID Correlation*

PCIe Function ID	NIC Port	vNIC Pipe	vNIC ID
4	0	3	x.3
6	0	4	x.4
1	1	1	x.1
3	1	2	x.2
5	1	3	x.3
7	1	4	x.4

In this, the *x* in the vNIC ID represents the switch port to which the NIC port is connected.

vNIC Bandwidth Metering

N/OS 8.2 supports bandwidth metering for vNIC traffic. By default, each of the four vNICs on any given port is allowed an equal share (25%) of NIC capacity when enabled. However, you may configure the percentage of available switch port bandwidth permitted to each vNIC.

vNIC bandwidth can be configured as a value from 1 to 100, with each unit representing 1% (or 100Mbps) of the 10Gbps link. By default, each vNICs enabled on a port is assigned 25 units (equal to 25% of the link, or 2.5Gbps). When traffic from the switch to the vNIC reaches its assigned bandwidth limit, the switch will drop packets egressing to the affected vNIC. Likewise, if traffic from the vNIC to the switch reaches its limit, the NIC will drop egress of any further packets. When traffic falls to less than the configured thresholds, traffic resumes at its allowed rate.

To change the bandwidth allocation, use the following commands:

```
RS 8264CS(config)# vnic port <port alias or number> index <vNIC number (1-4)>
RS 8264CS(vnic-config)# bandwidth <allocated percentage>
```

Note: vNICs that are disabled are automatically allocated a bandwidth value of 0.

A combined maximum of 100 units can be allocated among vNIC pipes enabled for any specific port (bandwidth values for disabled pipes are not counted). If more than 100 units are assigned to enabled pipes, an error will be reported when attempting to apply the configuration.

The bandwidth metering configuration is synchronized between the switch and vNICs. Once configured on the switch, there is no need to manually configure vNIC bandwidth metering limits on the NIC as long as it is in Lenovo Virtual Fabric mode.

vNIC Groups

vNICs can be grouped together, along with uplink ports and trunks, as well as other ports that were defined as server ports but not connected to vNICs. Each vNIC group is essentially a separate virtual network within the switch. Elements within a vNIC group have a common logical function and can communicate with each other, while elements in different vNIC groups are separated.

N/OS 8.2 supports up to 32 independent vNIC groups.

The VLAN configured for the vNIC group will be automatically assigned to member vNICs, ports, and trunks must not be manually configured for those elements.

Note: Once a VLAN is assigned to a vNIC group, that VLAN is used only for vNIC purposes and is no longer available for configuration. Likewise, any VLAN configured for regular purposes cannot be configured as a vNIC group VLAN.

Other vNIC group rules are as follows:

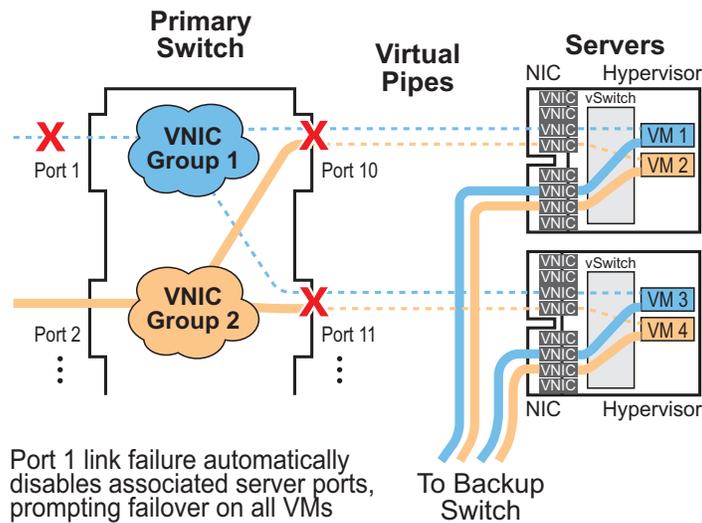

- vNIC groups may have one or more vNIC members. However, any given vNIC can be a member of only one vNIC group.
- All vNICs on a given port must belong to different vNIC groups.
- Uplink ports which are part of a trunk may not be individually added to a vNIC group. Only one individual uplink port one static trunk (consisting of multiple uplink ports) may be added to any given vNIC group.
- Because regular, inner VLAN IDs are ignored by the switch for traffic in vNIC groups, following rules and restrictions apply:
 - The inner VLAN tag may specify any VLAN ID in the full, supported range (1 to 4095) and may even duplicate outer vNIC group VLAN IDs.
 - Per-VLAN IGMP snooping is not supported in vNIC groups.
 - The inner VLAN tag is not processed in any way in vNIC groups: The inner tag cannot be stripped or added on egress port, is not used to restrict multicast traffic, is not matched against ACL filters, and does not influence Layer 3 switching.
 - For vNIC ports on the switch, because the outer vNIC group VLAN is transparent to the OS/hypervisor and upstream devices, configure VLAN tagging as normally required (on or off) for the those devices, ignoring any outer tag.
- Virtual machines (VMs) and other VEs associated with vNICs are automatically detected by the switch when VMready is enabled (see [“VMready” on page 227](#)). However, vNIC groups are isolated from other switch elements. VEs in vNIC groups cannot be assigned to VM groups.

vNIC Teaming Failover

For NIC failover in a non-virtualized environment, when a service group's uplink ports fail or are disconnected, the switch disables the affected group's server ports, causing the server to failover to the backup NIC and switch.

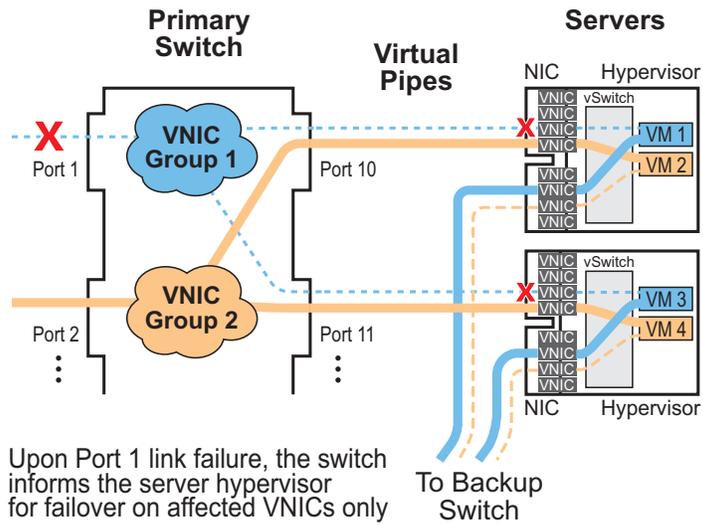

However, in a virtualized environment, disabling the affected server ports would disrupt all vNIC pipes on those ports, not just those that have lost their uplinks (see [Figure 25](#)).

Figure 25. Regular Failover in a Virtualized Environment

To avoid disrupting vNICs that have not lost their uplinks, N/OS 8.2 and the Emulex Virtual Fabric Adapter provide vNIC-aware failover. When a vNIC group's uplink ports fail, the switch cooperates with the affected NIC to prompt failover only on the appropriate vNICs. This allows the vNICs that are not affected by the failure to continue without disruption (see [Figure 26 on page 222](#)).

Figure 26. vNIC Failover Solution

By default, vNIC Teaming Failover is disabled on each vNIC group, but can be enabled or disabled independently for each vNIC group using the following commands:

```
RS 8264CS(config)# vnic vnicgroup <group number>
RS 8264CS(vnic-group-config)# failover
```

vNIC Configuration Example

Basic vNIC Configuration

Consider the following example configuration:

Figure 27. Multiple vNIC Groups

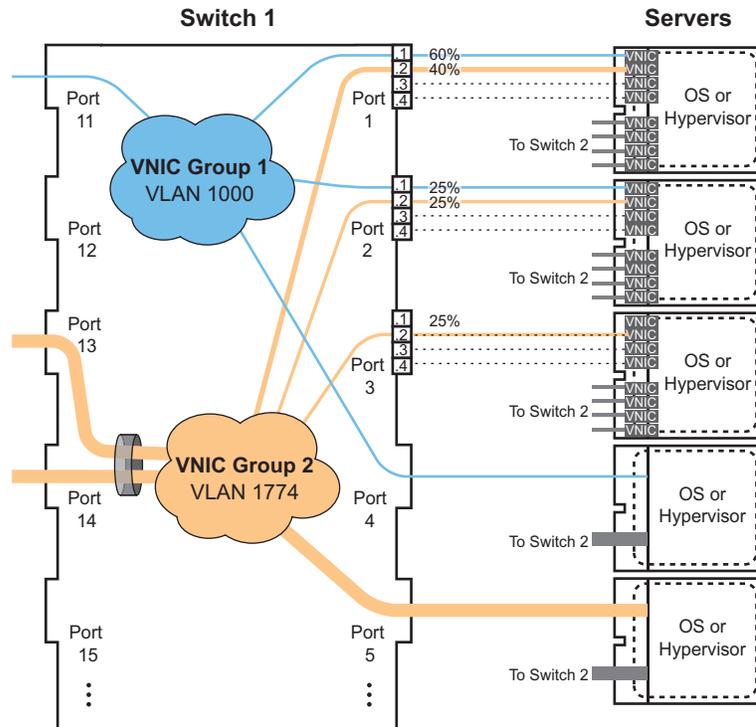

Figure 27 has the following vNIC network characteristics:

- vNIC group 1 has an outer tag for VLAN 1000. The group is comprised of vNIC pipes 1.1 and 2.1, switch server port 4 (a non-vNIC port), and uplink port 11.
- vNIC group 2 has an outer tag for VLAN 1774. The group is comprised of vNIC pipes 1.2, 2.2 and 3.2, switch server port 5, and an uplink trunk of ports 13 and 14.
- vNIC failover is enabled for both vNIC groups.
- vNIC bandwidth on port 1 is set to 60% for vNIC 1 and 40% for vNIC 2.
- Other enabled vNICs (2.1, 2.2, and 3.2) are permitted the default bandwidth of 25% (2.5Gbps) on their respective ports.
- All remaining vNICs are disabled (by default) and are automatically allocated 0 bandwidth.

1. Define the server ports.

```
RS 8264CS(config)# system server-ports port 1-5
```

2. Configure the external trunk to be used with vNIC group 2.

```
RS 8264CS(config)# portchannel 1 port 13,14
RS 8264CS(config)# portchannel 1 enable
```

3. Enable the vNIC feature on the switch.

```
RS 8264CS(config)# vnic enable
```

4. Configure the virtual pipes for the vNICs attached to each server port:

```
RS 8264CS(config)# vnic port 1 index 1 (Select vNIC 1 on the port)
RS 8264CS(vnic-config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic-config)# bandwidth 60 (Allow 60% egress bandwidth)
RS 8264CS(vnic-config)# exit
RS 8264CS(config)# vnic port 1 index 2 (Select vNIC 2 on the port)
RS 8264CS(vnic-config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic-config)# bandwidth 40 (Allow 40% egress bandwidth)
RS 8264CS(vnic-config)# exit

RS 8264CS(config)# vnic port 2 index 1 (Select vNIC 1 on the port)
RS 8264CS(vnic-config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic-config)# exit
RS 8264CS(config)# vnic port 2 index 2 (Select vNIC 2 on the port)
RS 8264CS(vnic-config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic-config)# exit
```

As a configuration shortcut, vNICs do not have to be explicitly enabled in this step. When a vNIC is added to the vNIC group (in the next step), the switch will prompt you to confirm automatically enabling the vNIC if it is not yet enabled (shown for 3.2).

Note: vNICs are not supported simultaneously on the same switch ports as VMready.

5. Add ports, trunks, and virtual pipes to their vNIC groups.

```
RS 8264CS(config)# vnic vnicgroup 1 (Select vNIC group)
RS 8264CS(vnic-group-config)# vlan 1000 (Specify the VLAN)
RS 8264CS(vnic-group-config)# member 1.1 (Add vNIC pipes to the group)
RS 8264CS(vnic-group-config)# member 2.1
RS 8264CS(vnic-group-config)# port 4 (Add non-vNIC port to the group)
RS 8264CS(vnic-group-config)# port 11 (Add uplink port to the group)
RS 8264CS(vnic-group-config)# failover (Enable vNIC failover for the group)
RS 8264CS(vnic-group-config)# enable (Enable the vNIC group)
RS 8264CS(vnic-group-config)# exit

RS 8264CS(config)# vnic vnicgroup 2
RS 8264CS(vnic-group-config)# vlan 1774
RS 8264CS(vnic-group-config)# member 1.2
RS 8264CS(vnic-group-config)# member 2.2
RS 8264CS(vnic-group-config)# member 3.2
vNIC 3.2 is not enabled.
Confirm enabling vNIC3.2 [y/n]: y
RS 8264CS(vnic-group-config)# port 5
RS 8264CS(vnic-group-config)# trunk 1
RS 8264CS(vnic-group-config)# failover
RS 8264CS(vnic-group-config)# enable
RS 8264CS(vnic-group-config)# exit
```

Once VLAN 1000 and 1774 are configured for vNIC groups, they will not be available for configuration in the regular VLAN menus (RS 8264CS(config)# vlan <VLAN number>).

Note: vNICs are not supported simultaneously on the same switch ports as VMready.

6. Save the configuration.

vNICs for iSCSI on Emulex Endeavor 2

The N/OS vNIC feature works with standard network applications like iSCSI as previously described. However, the Emulex Endeavor 2 NIC expects iSCSI traffic to occur only on a single vNIC pipe. When using the Emulex Endeavor 2, only vNIC pipe 2 may participate in iSCSI.

To configure the switch for this solution, place iSCSI traffic in its own vNIC group, comprised of the uplink port leading to the iSCSI target, and the related <port>.2 vNIC pipes connected to the participating servers. For example:

1. Define the server ports.

```
RS 8264CS(config)# system server-ports port 1-3
```

2. Enable the vNIC feature on the switch.

```
RS 8264CS # vnic enable
```

3. Configure the virtual pipes for the iSCSI vNICs attached to each server port:

```
RS 8264CS(config)# vnic port 1 index 2 (Select vNIC 2 on the server port)
RS 8264CS(vnic_config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic_config)# exit
RS 8264CS(config)# vnic port 2 index 2 (Select vNIC 2 on the server port)
RS 8264CS(vnic_config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic_config)# exit
RS 8264CS(config)# vnic port 3 index 2 (Select vNIC 2 on the server port)
RS 8264CS(vnic_config)# enable (Enable the vNIC pipe)
RS 8264CS(vnic_config)# exit
```

Note: vNICs are not supported simultaneously on the same switch ports as VMready.

4. Add ports and virtual pipes to a vNIC group.

```
RS 8264CS(config)# vnic vnicgroup 1 (Select vNIC group)
RS 8264CS(vnic-group-config)# vlan 1000 (Specify the VLAN)
RS 8264CS(vnic-group-config)# member 1.2 (Add iSCSI vNIC pipes to the group)
RS 8264CS(vnic-group-config)# member 2.2
RS 8264CS(vnic-group-config)# member 3.2
RS 8264CS(vnic-group-config)# port 4 (Add the uplink port to the group)
RS 8264CS(vnic-group-config)# enable (Enable the vNIC group)
RS 8264CS(vnic-group-config)# exit
```

5. Save the configuration.

Chapter 16. VMready

Virtualization is used to allocate server resources based on logical needs, rather than on strict physical structure. With appropriate hardware and software support, servers can be virtualized to host multiple instances of operating systems, known as virtual machines (VMs). Each VM has its own presence on the network and runs its own service applications.

Software known as a *hypervisor* manages the various virtual entities (VEs) that reside on the host server: VMs, virtual switches, and so on. Depending on the virtualization solution, a virtualization management server may be used to configure and manage multiple hypervisors across the network. With some solutions, VMs can even migrate between host hypervisors, moving to different physical hosts while maintaining their virtual identity and services.

The Lenovo Networking OS 8.2 VMready feature supports up to 2048 VEs in a virtualized data center environment. The switch automatically discovers the VEs attached to switch ports, and distinguishes between regular VMs, Service Console Interfaces, and Kernel/Management Interfaces in a VMware® environment.

VEs may be placed into VM groups on the switch to define communication boundaries: VEs in the same VM group may communicate with each other, while VEs in different groups may not. VM groups also allow for configuring group-level settings such as virtualization policies and ACLs.

The administrator can also pre-provision VEs by adding their MAC addresses (or their IPv4 address or VM name in a VMware environment) to a VM group. When a VE with a pre-provisioned MAC address becomes connected to the switch, the switch will automatically apply the appropriate group membership configuration.

The G8264CS with VMready also detects the migration of VEs across different hypervisors. As VEs move, the G8264CS NMotion™ feature automatically moves the appropriate network configuration as well. NMotion gives the switch the ability to maintain assigned group membership and associated policies, even when a VE moves to a different port on the switch.

VMready also works with VMware Virtual Center (vCenter) management software. Connecting with a vCenter allows the G8264CS to collect information about more distant VEs, synchronize switch and VE configuration, and extend migration properties.

Note: VM groups and policies, VE pre-provisioning, and VE migration features are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

VE Capacity

When VMready is enabled, the switch will automatically discover VEs that reside in hypervisors directly connected on the switch ports. Lenovo N/OS 8.2 supports up to 2048 VEs. Once this limit is reached, the switch will reject additional VEs.

Note: In rare situations, the switch may reject new VEs prior to reaching the supported limit. This can occur when the internal hash corresponding to the new VE is already in use. If this occurs, change the MAC address of the VE and retry the operation. The MAC address can usually be changed from the virtualization management server console (such as the VMware Virtual Center).

Defining Server Ports

Before you configure VMready features, you must first define whether ports are connected to servers or are used as uplink ports. Use the following ISCLI configuration command to define a port as a server port:

```
RS 8264CS(config)# system server-ports port <port alias or number>
```

Ports that are not defined as server ports are automatically considered uplink ports.

VM Group Types

VEs, as well as switch server ports, switch uplink ports, static trunks, and LACP trunks, can be placed into VM groups on the switch to define virtual communication boundaries. Elements in a given VM group are permitted to communicate with each other, while those in different groups are not. The elements within a VM group automatically share certain group-level settings.

N/OS 8.2 supports up to 32 VM groups. There are two different types:

- Local VM groups are maintained locally on the switch. Their configuration is not synchronized with hypervisors.
- Distributed VM groups are automatically synchronized with a virtualization management server (see [“Assigning a vCenter” on page 239](#)).

Each VM group type is covered in detail in the following sections.

Note: VM groups are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

Local VM Groups

The configuration for local VM groups is maintained on the switch (locally) and is not directly synchronized with hypervisors. Local VM groups may include only local elements: local switch ports and trunks, and only those VEs connected to one of the switch ports or pre-provisioned on the switch.

Local VM groups support limited VE migration: as VMs and other VEs move to different hypervisors connected to different ports on the switch, the configuration of their group identity and features moves with them. However, VE migration to and from more distant hypervisors (those not connected to the G8264CS, may require manual configuration when using local VM groups.

Configuring a Local VM Group

Use the following ISCLI configuration commands to assign group properties and membership:

```
RS 8264CS(config)# virt vmgroup <VM group number> ?
  cpu                               (Enable sending unregistered IPMC to CPU)
  flood                             (Enable flooding unregistered IPMC)
  key <LACP trunk key>              (Add LACP trunk to group)
  optflood                          (Enable optimized flooding)
  port <port alias or number>        (Add port member to group)
  portchannel <trunk group number>   (Add static trunk to group)
  profile <profile name>             (Not used for local groups)
  stg <Spanning Tree group>          (Add STG to group)
  tag                                (Set VLAN tagging on ports)
  validate <advanced|basic>         (Validate mode for the group)
  vlan <VLAN number>                (Specify the group VLAN)
  vm <MAC>|<index>|<UUID>|<IPv4 address>|<name>(Add VM member to group)
  vmap <VMAP number> [intports|extports] (Specify VMAP number)
```

The following rules apply to the local VM group configuration commands:

- `cpu`: Enable sending unregistered IPMC to CPU.
- `flood`: Enable flooding unregistered IPMC.
- `key`: Add LACP trunks to the group.
- `optflood`: Enable optimized flooding to allow sending unregistered IPMC to the Mrouter ports without having any packet loss during the learning period; This option is disabled by default; When `optflood` is enabled, the `flood` and `cpu` settings are ignored.
- `port`: Add switch server ports or switch uplink ports to the group. Note that VM groups and vNICs (see [“Virtual NICs” on page 217](#)) are not supported simultaneously on the same port.
- `portchannel`: Add static port trunks to the group.
- `profile`: The profile options are not applicable to local VM groups. Only distributed VM groups may use VM profiles (see [“VM Profiles” on page 232](#)).
- `stg`: The group may be assigned to a Spanning-Tree group for broadcast loop control (see [“Spanning Tree Protocols” on page 153](#)).
- `tag`: Enable VLAN tagging for the VM group. If the VM group contains ports which also exist in other VM groups, enable tagging in both VM groups.
- `validate`: Set validation mode for the group.
- `vlan`: Each VM group must have a unique VLAN number. This is required for local VM groups. If one is not explicitly configured, the switch will automatically assign the next unconfigured VLAN when a VE or port is added to the VM group.
- `vmap`: Each VM group may optionally be assigned a VLAN-based ACL (see [“VLAN Maps” on page 243](#)).
- `vm`: Add VMs.

VMs and other VEs are primarily specified by MAC address. They can also be specified by UUID, IP address, or by the index number as shown in various VMready information output (see [“VMready Information Displays” on page 246](#)).

If VMware Tools software is installed in the guest operating system (see VMware documentation for information on installing recommended tools), VEs may also be specified by IPv4 address or VE name. However, if there is more than one possible VE for the input (such as an IPv4 address for a VM that uses multiple vNICs), the switch will display a list of candidates and prompt for a specific MAC address.

Only VEs currently connected to the switch port (local) or pending connection (pre-provisioned) are permitted in local VM groups.

Because VM groups and vNIC groups (see [“Virtual NICs” on page 217](#)) are isolated from each other, VMs detected on vNICs cannot be assigned to VM groups.

Use the `no` variant of the commands to remove or disable VM group configuration settings:

```
RS 8264CS(config)# no virt vgroup <VM group number> [?]
```

Note: Local VM groups are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

Distributed VM Groups

Distributed VM groups allow configuration profiles to be synchronized between the G8264CS and associated hypervisors and VEs. This allows VE configuration to be centralized, and provides for more reliable VE migration across hypervisors.

Using distributed VM groups requires a virtualization management server. The management server acts as a central point of access to configure and maintain multiple hypervisors and their VEs (VMs, virtual switches, and so on).

The G8264CS must connect to a virtualization management server before distributed VM groups can be used. The switch uses this connection to collect configuration information about associated VEs, and can also automatically push configuration profiles to the virtualization management server, which in turn configures the hypervisors and VEs. See [“Virtualization Management Servers” on page 239](#) for more information.

Note: Distributed VM groups are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

VM Profiles

VM profiles are required for configuring distributed VM groups. They are not used with local VM groups. A VM profile defines the VLAN and virtual switch bandwidth shaping characteristics for the distributed VM group. The switch distributes these settings to the virtualization management server, which in turn distributes them to the appropriate hypervisors for VE members associated with the group.

Creating VM profiles is a two part process. First, the VM profile is created as shown in the following command on the switch:

```
RS 8264CS(config)# virt vmprofile <profile name>
```

Next, the profile must be edited and configured using the following configuration commands:

```
RS 8264CS(config)# virt vmprofile edit <profile name> ?
eshaping <average bandwidth> <burst size> <peak>
shaping <average bandwidth> <burst size> <peak>
vlan <VLAN number>
```

For virtual switch bandwidth shaping parameters, average and peak bandwidth are specified in kilobits per second (a value of 1000 represents 1 Mbps). Burst size is specified in kilobytes (a value of 1000 represents 1 MB). Eshaping (egress shaping) is used for distributed virtual switch.

Note: The bandwidth shaping parameters in the VM profile are used by the hypervisor virtual switch software. To set bandwidth policies for individual VEs, see [“VM Policy Bandwidth Control” on page 244](#).

Once configured, the VM profile may be assigned to a distributed VM group as shown in the following section.

Initializing a Distributed VM Group

Note: A VM profile is required before a distributed VM group may be configured. See “[VM Profiles](#)” on page 232 for details.

Once a VM profile is available, a distributed VM group may be initialized using the following configuration command:

```
RS 8264CS(config)# virt vmgroup <VM group number> profile <VM profile name>
```

Only one VM profile can be assigned to a given distributed VM group. To change the VM profile, the old one must first be removed using the following ISCLI configuration command:

```
RS 8264CS(config)# no virt vmgroup <VM group number> profile
```

Note: The VM profile can be added only to an empty VM group (one that has no VLAN, VMs, or port members). Any VM group number currently configured for a local VM group (see “[Local VM Groups](#)” on page 229) cannot be converted and must be deleted before it can be used for a distributed VM group.

Assigning Members

VMs, ports, and trunks may be added to the distributed VM group only after the VM profile is assigned. Group members are added, pre-provisioned, or removed from distributed VM groups in the same manner as with local VM groups (“[Local VM Groups](#)” on page 229), with the following exceptions:

- VMs: VMs and other VEs are not required to be local. Any VE known by the virtualization management server can be part of a distributed VM group.
- The VM group `vlan` option (see [page 230](#)) cannot be used with distributed VM groups. For distributed VM groups, the VLAN is assigned in the VM profile.

Synchronizing the Configuration

When the configuration for a distributed VM group is modified, the switch updates the assigned virtualization management server. The management server then distributes changes to the appropriate hypervisors.

For VM membership changes, hypervisors modify their internal virtual switch port groups, adding or removing server port memberships to enforce the boundaries defined by the distributed VM groups. Virtual switch port groups created in this fashion can be identified in the virtual management server by the name of the VM profile, formatted as follows:

```
Lenovo_<VM profile name>
```

(or)

```
Lenovo_<VM profile name> <index number> (for vDS)
```

Adding a server host interface to a distributed VM group does not create a new port group on the virtual switch or move the host. Instead, because the host interface already has its own virtual switch port group on the hypervisor, the VM profile settings are applied to its existing port group.

Note: When applying the distributed VM group configuration, the virtualization management server and associated hypervisors must take appropriate actions. If a hypervisor is unable to make requested changes, an error message will be displayed on the switch. Be sure to evaluate all error message and take the appropriate actions for the expected changes to apply.

Removing Member VEs

Removing a VE from a distributed VM group on the switch will have the following effects on the hypervisor:

- The VE will be moved to the `Lenovo_Default` port group in VLAN 0 (zero).
- Traffic shaping will be disabled for the VE.
- All other properties will be reset to default values inherited from the virtual switch.

VMcheck

The G8264CS primarily identifies virtual machines by their MAC addresses. An untrusted server or a VM could identify itself by a trusted MAC address leading to MAC spoofing attacks. Sometimes, MAC addresses get transferred to another VM, or they get duplicated.

The VMcheck solution addresses these security concerns by validating the MAC addresses assigned to VMs. The switch periodically sends hello messages on server ports. These messages include the switch identifier and port number. The hypervisor listens to these messages on physical NICs and stores the information, which can be retrieved using the VMware Infrastructure Application Programming Interface (VI API). This information is used to validate VM MAC addresses. Two modes of validation are available: Basic and Advanced.

Use the following command to select the validation mode or to disable validation:

```
RS 8264CS(config)# [no] virt vmgroup <VM group number> validate  
{basic|advanced}
```

Basic Validation

This mode provides port-based validation by identifying the port used by a hypervisor. It is suitable for environments in which MAC reassignment or duplication cannot occur.

The switch, using the hello message information, identifies a hypervisor port. If the hypervisor port is found in the hello message information, it is deemed to be a trusted port. Basic validation should be enabled when:

- A VM is added to a VM group, and the MAC address of the VM interface is in the Layer 2 table of the switch.
- A VM interface that belongs to a VM group experiences a “source miss” i.e. is not able to learn new MAC address.
- A trusted port goes down. Port validation must be performed to ensure that the port does not get connected to an untrusted source when it comes back up.

Use the following command to set the action to be performed if the switch is unable to validate the VM MAC address:

```
RS 8264CS(config)# virt vmcheck action basic {log|link}  
  
log - generates a log  
link - disables the port
```

Advanced Validation

This mode provides VM-based validation by mapping a switch port to a VM MAC address. It is suitable for environments in which spoofing, MAC reassignment, or MAC duplication is possible.

When the switch receives frames from a VM, it first validates the VM interface based on the VM MAC address, VM Universally Unique Identifier (UUID), Switch port, and Switch ID available in the hello message information. Only if all the four parameters are matched, the VM MAC address is considered valid.

In advanced validation mode, if the VM MAC address validation fails, an ACL can be automatically created to drop the traffic received from the VM MAC address on the switch port. Use the following command to specify the number of ACLs to be automatically created for dropping traffic:

```
RS 8264CS(config)# virt vmcheck acls max <1-256>
```

Use the following command to set the action to be performed if the switch is unable to validate the VM MAC address:

```
RS 8264CS(config)# virt vmcheck action advanced {log|link|acl}
```

Following are the other VMcheck commands:

Table 22. VMcheck Commands

Command	Description
RS 8264CS(config)# virt vmware hello {enable hport <port number> haddr htimer}	Hello messages setting: enable/add port/advertise this IP address in the hello messages instead of the default management IP address/set the timer to send the hello messages
RS 8264CS(config)# no virt vmware hello {enable hport <port number>}	Disable hello messages/remove port
RS 8264CS(config)# [no] virt vmcheck trust <port number or range>	Mark a port as trusted; Use the no form of the command to mark port as untrusted
RS 8264CS# no virt vmcheck acls	ACLs cannot be used for VMcheck

Virtual Distributed Switch

A virtual Distributed Switch (vDS) allows the hypervisor's NIC to be attached to the vDS instead of its own virtual switch. The vDS connects to the vCenter and spans across multiple hypervisors in a datacenter. The administrator can manage virtual machine networking for the entire data center from a single interface. The vDS enables centralized provisioning and administration of virtual machine networking in the data center using the VMware vCenter server.

When a member is added to a distributed VM group, a distributed port group is created on the vDS. The member is then added to the distributed port group.

Distributed port groups on a vDS are available to all hypervisors that are connected to the vDS. Members of a single distributed port group can communicate with each other.

Note: vDS works with ESX 4.0 or higher versions.

To add a vDS, use the command:

```
RS 8264CS# virt vmware dvswitch add <datacenter name> <dvSwitch name>
[ <dvSwitch-version>]
```

Prerequisites

Before adding a vDS on the G8264CS, ensure the following:

- VMware vCenter is fully installed and configured and includes a "bladevm" administration account and a valid SSL certificate.
- A virtual distributed switch instance has been created on the vCenter. The vDS version must be higher or the same as the hypervisor version on the hosts.
- At least two hypervisors are configured.

Guidelines

Before migrating VMs to a vDS, consider the following:

- At any one time, a VM NIC can be associated with only one virtual switch: to the hypervisor's virtual switch, or to the vDS.
- Management connection to the server must be ensured during the migration. The connection is via the Service Console or the Kernel/Management Interface.
- The vDS configuration and migration can be viewed in vCenter at the following locations:
 - vDS: Home > Inventory > Networking
 - vDS Hosts: Home > Inventory > Networking > vDS > Hosts

Note: These changes will not be displayed in the running configuration on the G8264CS.

Migrating to vDS

You can migrate VMs to the vDS using vCenter. The migration may also be accomplished using the operational commands on the G8264CS available in the following CLI menus:

For VMware vDS operations:

```
RS 8264CS# virt vmware dvswitch ?
add                Add a dvSwitch to a DataCenter
addhost            Add a host to a dvSwitch
adduplnk           Add a physical NIC to dvSwitch uplink ports
del                Remove a dvSwitch from a DataCenter
remhost            Remove a host from a dvSwitch
remuplnk           Remove a physical NIC from dvSwitch uplink ports
```

For VMware distributed port group operations:

```
RS 8264CS# virt vmware dpg ?
add                Add a port group to a dvSwitch
del                Delete a port group from a dvSwitch
update             Update a port group on a dvSwitch
vmac               Change a VM NIC's port group
```

Virtualization Management Servers

The G8264CS can connect with a virtualization management server to collect configuration information about associated VEs. The switch can also automatically push VM group configuration profiles to the virtualization management server, which in turn configures the hypervisors and VEs, providing enhanced VE mobility.

One virtual management server must be assigned on the switch before distributed VM groups may be used. N/OS 8.2 currently supports only the VMware Virtual Center (vCenter).

Note: Although VM groups and policies are not supported simultaneously on the same ports as vNICs (“Virtual NICs” on page 217), vCenter synchronization can provide additional information about VEs on vNIC and non-vNIC ports.

Assigning a vCenter

Assigning a vCenter to the switch requires the following:

- The vCenter must have a valid IPv4 address which is accessible to the switch (IPv6 addressing is not supported for the vCenter).
- A user account must be configured on the vCenter to provide access for the switch. The account must have (at a minimum) the following vCenter user privileges:
 - Network
 - Host Network > Configuration
 - Virtual Machine > Modify Device Settings

Once vCenter requirements are met, the following configuration command can be used on the G8264CS to associate the vCenter with the switch:

```
RS 8264CS(config)# virt vmware vcspec <vCenter IPv4 address> <username> [noauth]
```

This command specifies the IPv4 address and account username that the switch will use for vCenter access. Once entered, the administrator will be prompted to enter the password for the specified vCenter account.

The `noauth` option causes the switch to ignore SSL certificate authentication. This is required when no authoritative SSL certificate is installed on the vCenter.

Note: By default, the vCenter includes only a self-signed SSL certificate. If using the default certificate, the `noauth` option is required.

Once the vCenter configuration has been applied on the switch, the G8264CS will connect to the vCenter to collect VE information.

vCenter Scans

Once the vCenter is assigned, the switch will periodically scan the vCenter to collect basic information about all the VEs in the datacenter, and more detailed information about the local VEs that the switch has discovered attached to its own ports.

The switch completes a vCenter scan approximately every two minutes. Any major changes made through the vCenter may take up to two minutes to be reflected on the switch. However, you can force an immediate scan of the vCenter by using one of the following ISCLI privileged EXEC commands:

```
RS 8264CS# virt vmware scan           (Scan the vCenter)
-or-
RS 8264CS# show virt vm -v -r       (Scan vCenter and display result)
```

Deleting the vCenter

To detach the vCenter from the switch, use the following configuration command:

```
RS 8264CS(config)# no virt vmware vcspec
```

Note: Without a valid vCenter assigned on the switch, any VE configuration changes must be manually synchronized.

Deleting the assigned vCenter prevents synchronizing the configuration between the G8264CS and VEs. VEs already operating in distributed VM groups will continue to function as configured, but any changes made to any VM profile or distributed VM group on the switch will affect only switch operation; changes on the switch will not be reflected in the vCenter or on the VEs. Likewise, any changes made to VE configuration on the vCenter will no longer be reflected on the switch.

Exporting Profiles

VM profiles for discovered VEs in distributed VM groups are automatically synchronized with the virtual management server and the appropriate hypervisors. However, VM profiles can also be manually exported to specific hosts before individual VEs are defined on them.

By exporting VM profiles to a specific host, virtual machine port groups will be available to the host's internal virtual switches so that new VMs may be configured to use them.

VM migration requires that the target hypervisor includes all the virtual switch port groups to which the VM connects on the source hypervisor. The VM profile export feature can be used to distribute the associated port groups to all the potential hosts for a given VM.

A VM profile can be exported to a host using the following ISCLI privileged EXEC command:

```
RS 8264CS# virt vmware export <VM profile name> <host list> <virtual switch name>
```

The host list can include one or more target hosts, specified by host name, IPv4 address, or UUID, with each list item separated by a space.

Once executed, the requisite port group will be created on the specified virtual switch. If the specified virtual switch does not exist on the target host, the port group will not be created.

VMware Operational Commands

The G8264CS may be used as a central point of configuration for VMware virtual switches and port groups using the following ISCLI privileged EXEC commands:

```
RS 8264CS# virt vmware ?  
dpg          Distributed port group operations  
dvswitch     VMWare dvSwitch operations  
export       Create or update a vm profile on one host  
pg           Add a port group to a host  
scan         Perform a VM Agent scan operation now  
updpg        Update a port group on a host  
vmacpg       Change a vnic's port group  
vsw          Add a vswitch to a host
```

Pre-Provisioning VEs

VEs may be manually added to VM groups in advance of being detected on the switch ports. By pre-provisioning the MAC address of VEs that are not yet active, the switch will be able to later recognize the VE when it becomes active on a switch port, and immediately assign the proper VM group properties without further configuration.

Undiscovered VEs are added to or removed from VM groups using the following configuration commands:

```
RS 8264CS(config)# [no] virt vmgroup <VM group number> vm <VE MAC address>
```

For the pre-provisioning of undiscovered VEs, a MAC address is required. Other identifying properties, such as IPv4 address or VM name permitted for known VEs, cannot be used for pre-provisioning.

Note: Because VM groups are isolated from vNIC groups (see [“vNIC Groups” on page 220](#)), pre-provisioned VEs that appear on vNIC ports will not be added to the specified VM group upon discovery.

VLAN Maps

A VLAN map (VMAP) is a type of Access Control List (ACL) that is applied to a VLAN or VM group rather than to a switch port as with regular ACLs (see [“Access Control Lists” on page 105](#)). In a virtualized environment, VMAPs allow you to create traffic filtering and metering policies that are associated with a VM group VLAN, allowing filters to follow VMs as they migrate between hypervisors.

Note: VLAN maps for VM groups are not supported simultaneously on the same ports as vNICs (see [“Virtual NICs” on page 217](#)).

N/OS 8.2 supports up to 128 VMAPs.

Individual VMAP filters are configured in the same fashion as regular ACLs, except that VLANs cannot be specified as a filtering criteria (unnecessary, since VMAPs are assigned to a specific VLAN or associated with a VM group VLAN).

VMAPs are configured using the following ISCLI configuration command path:

```
RS 8264CS(config)# access-control vmap <VMAP ID> ?
  action          Set filter action
  egress-port     Set to filter for packets egressing this port
  ethernet        Ethernet header options
  ipv4            IP version 4 header options
  meter           ACL metering configuration
  mirror          Mirror options
  packet-format   Set to filter specific packet format types
  re-mark         ACL re-mark configuration
  statistics      Enable access control list statistics
  tcp-udp         TCP and UDP filtering options
```

Once a VMAP filter is created, it can be assigned or removed using the following commands:

- For regular VLANs, use config-vlan mode:

```
RS 8264CS(config)# vlan <VLAN ID>
RS 8264CS(config-vlan)# [no] vmap <VMAP ID> [serverports |
non-serverports]
```

- For a VM group, use the global configuration mode:

```
RS 8264CS(config)# [no] virt vmgroup <ID> vmap <VMAP ID>
[serverports|non-serverports]
```

Note: Each VMAP can be assigned to only one VLAN or VM group. However, each VLAN or VM group may have multiple VMAPs assigned to it.

The optional `serverports` or `non-serverports` parameter can be specified to apply the action (to add or remove the VMAP) for either the switch server ports (`serverports`) or switch uplink ports (`non-serverports`). If omitted, the operation will be applied to all ports in the associated VLAN or VM group.

Note: VMAPs have a lower priority than port-based ACLs. If both an ACL and a VMAP match a particular packet, both filter actions will be applied as long as there is no conflict. In the event of a conflict, the port ACL will take priority, though switch statistics will count matches for both the ACL and VMAP.

VM Policy Bandwidth Control

In a virtualized environment where VEs can migrate between hypervisors and thus move among different ports on the switch, traffic bandwidth policies must be attached to VEs, rather than to a specific switch port.

VM Policy Bandwidth Control allows the administrator to specify the amount of data the switch will permit to flow from a particular VE, without defining a complicated matrix of ACLs or VMAPs for all port combinations where a VE may appear.

VM Policy Bandwidth Control Commands

VM Policy Bandwidth Control can be configured using the following configuration commands:

```
RS 8264CS(config)# virt vmpolicy vmbwidth <VM MAC>|<index>|<UUID>| <IPv4
address>|<name>?
txrate <committed rate> <burst> [<ACL number>]
                                     (Set the VM transmit bandwidth -
                                     ingress for switch)
rxrate <committed rate> <burst>      (Set the VM receive bandwidth - egress for switch)
bwctrl                                 (Enable bandwidth control)
```

Bandwidth allocation can be defined for transmit (TX) traffic or receive (RX) traffic. Because bandwidth allocation is specified from the perspective of the VE, the switch command for TX Rate Control (`txrate`) sets the data rate to be sent from the VM to the switch, and the RX rate sets the data rate to be received by the VM from the switch.

The *committed rate* is specified in multiples of 64 kbps, from 64 to 10,000,000. The maximum *burst* rate is specified as 32, 64, 128, 256, 1024, 2048, or 4096 kb. If both the committed rate and burst are set to 0, bandwidth control will be disabled.

When `txrate` is specified, the switch automatically selects an available ACL for internal use with bandwidth control. Optionally, if automatic ACL selection is not desired, a specific ACL may be selected. If there are no unassigned ACLs available, `txrate` cannot be configured.

Bandwidth Policies vs. Bandwidth Shaping

VM Profile Bandwidth Shaping differs from VM Policy Bandwidth Control.

VM Profile Bandwidth Shaping (see “[VM Profiles](#)” on page 232) is configured per VM group and is enforced on the server by a virtual switch in the hypervisor. Shaping is unidirectional and limits traffic transmitted from the virtual switch to the G8264CS. Shaping is performed prior to transmit VM Policy Bandwidth Control. If the egress traffic for a virtual switch port group exceeds shaping parameters, the traffic is dropped by the virtual switch in the hypervisor. Shaping uses server CPU resources, but prevents extra traffic from consuming bandwidth between the server and the G8264CS. Shaping is not supported simultaneously on the same ports as vNICs.

VM Policy Bandwidth Control is configured per VE, and can be set independently for transmit traffic. Bandwidth policies are enforced by the G8264CS. VE traffic that exceeds configured levels is dropped by the switch upon ingress. Setting `txrate` uses ACL resources on the switch.

Bandwidth shaping and bandwidth policies can be used separately or in concert.

VMready Information Displays

The G8264CS can be used to display a variety of VMready information.

Note: Some displays depict information collected from scans of a VMware vCenter and may not be available without a valid vCenter. If a vCenter is assigned (see [“Assigning a vCenter” on page 239](#)), scan information might not be available for up to two minutes after the switch boots or when VMready is first enabled. Also, any major changes made through the vCenter may take up to two minutes to be reflected on the switch unless you force an immediate vCenter scan (see [“vCenter Scans” on page 239](#)).

Local VE Information

A concise list of local VEs and pre-provisioned VEs is available with the following ISCLI privileged EXEC command:

```
RS 8264CS# show virt vm

IP Address          VMAC Address          Index Port    VM Group (Profile)
-----
*172.16.46.50      00:50:56:4e:62:00     4      3
*172.16.46.10      00:50:56:4f:f2:00     2      4
+172.16.46.51      00:50:56:72:ec:00     1      3
+172.16.46.11      00:50:56:7c:1c:00     3      4
172.16.46.25       00:50:56:9c:00:00     5      4
172.16.46.15       00:50:56:9c:21:00     0      4
172.16.46.35       00:50:56:9c:29:00     6      3
172.16.46.45       00:50:56:9c:47:00     7      3

Number of entries: 8
* indicates VMware ESX Service Console Interface
+ indicates VMware ESX/ESXi VMKernel or Management Interface
```

Note: The Index numbers shown in the VE information displays can be used to specify a particular VE in configuration commands.

If a vCenter is available, more verbose information can be obtained using the following ISCLI privileged EXEC command option:

```

RS 8264CS# show virt vm -v

```

Index	MAC Address, IP Address	Name (VM or Host), @Host (VMs only)	Port, VLAN	Group	Vswitch, Port Group

```

To view additional detail regarding any specific VE, see [“vCenter VE Details” on page 249](#)).

vCenter Hypervisor Hosts

If a vCenter is available, the following ISCLI privileged EXEC command displays the name and UUID of all VMware hosts, providing an essential overview of the data center:

```

RS 8264CS# show virt vmware hosts

```

UUID	Name(s), IP Address
00a42681-d0e5-5910-a0bf-bd23bd3f7800	172.16.41.30
002e063c-153c-dd11-8b32-a78dd1909a00	172.16.46.10
00f1fe30-143c-dd11-84f2-a8ba2cd7ae00	172.16.44.50
0018938e-143c-dd11-9f7a-d8defa4b8300	172.16.46.20
...	

Using the following command, the administrator can view more detailed vCenter host information, including a list of virtual switches and their port groups, as well as details for all associated VEs:

```

RS 8264CS# show virt vmware showhost {<UUID>|<IPv4 address>|<host name>}
Vswitches available on the host:
    vSwitch0
Port Groups and their Vswitches on the host:
    BNT_Default          vSwitch0
    VM Network           vSwitch0
    Service Console      vSwitch0
    VMkernel              vSwitch0
-----
MAC Address      00:50:56:9c:21:2f
Port             4
Type             Virtual Machine
VM vCenter Name  halibut
VM OS hostname   localhost.localdomain
VM IP Address    172.16.46.15
VM UUID          001c41f3-ccd8-94bb-1b94-6b94b03b9200
Current VM Host  172.16.46.10
Vswitch          vSwitch0
Port Group       BNT_Default
VLAN ID          0
...

```

vCenter VEs

If a vCenter is available, the following ISCLI privileged EXEC command displays a list of all known VEs:

```

RS 8264CS# show virt vmware vms
UUID                               Name(s), IP Address
-----

001c4312-a145-bf44-7edd-49b7a2fc3800  vm3
001caf40-a40a-de6f-7b44-9c496f123b00  30VM7

```

vCenter VE Details

If a vCenter is available, the following ISCLI privileged EXEC command displays detailed information about a specific VE:

```
RS 8264CS# show virt vmware showvm {<VM UUID>|<VM IPv4 address>|<VM name>}
-----
MAC Address      00:50:56:9c:21:2f
Port             4
Type             Virtual Machine
VM vCenter Name  halibut
VM OS hostname   localhost.localdomain
VM IP Address    172.16.46.15
VM UUID          001c41f3-ccd8-94bb-1b94-6b94b03b9200
Current VM Host  172.16.46.10
Vswitch          vSwitch0
Port Group       BNT_Default
VLAN ID          0
```

VMready Configuration Example

This example has the following characteristics:

- A VMware vCenter is fully installed and configured prior to VMready configuration and includes a “bladevm” administration account and a valid SSL certificate.
- The distributed VM group model is used.
- The VM profile named “Finance” is configured for VLAN 30, and specifies NIC-to-switch bandwidth shaping for 1Mbps average bandwidth, 2MB bursts, and 3Mbps maximum bandwidth.
- The VM group includes four discovered VMs on switch server ports 1 and 2, and one static trunk (previously configured) that includes switch uplink ports 3 and 4.

1. Define the server ports.

```
RS 8264CS(config)# system server-ports port 1-2
```

2. Enable the VMready feature.

```
RS 8264CS(config)# virt enable
```

3. Specify the VMware vCenter IPv4 address.

```
RS 8264CS(config)# virt vmware vmware vcspec 172.16.100.1 bladevm
```

When prompted, enter the user password that the switch must use for access to the vCenter.

4. Create the VM profile.

```
RS 8264CS(config)# virt vmprofile Finance
RS 8264CS(config)# virt vmprofile edit Finance vlan 30
RS 8264CS(config)# virt vmprofile edit Finance shaping 1000 2000 3000
```

5. Define the VM group.

```
RS 8264CS(config)# virt vmgroup 1 profile Finance
RS 8264CS(config)# virt vmgroup 1 vm arctic
RS 8264CS(config)# virt vmgroup 1 vm monster
RS 8264CS(config)# virt vmgroup 1 vm sierra
RS 8264CS(config)# virt vmgroup 1 vm 00:50:56:4f:f2:00
RS 8264CS(config)# virt vmgroup 1 portchannel 1
```

When VMs are added, the server ports on which they appear are automatically added to the VM group. In this example, there is no need to manually add ports 1 and 2.

Note: VM groups and vNICs (see “Virtual NICs” on page 217) are not supported simultaneously on the same switch ports.

6. If necessary, enable VLAN tagging for the VM group:

```
RS 8264CS(config)# virt vmgroup 1 tag
```

Note: If the VM group contains ports that also exist in other VM groups, make sure tagging is enabled in both VM groups. In this example configuration, no ports exist in more than one VM group.

7. Save the configuration.

Chapter 17. FCoE and CEE

This chapter provides conceptual background and configuration examples for using Converged Enhanced Ethernet (CEE) features of the RackSwitch G8264CS, with an emphasis on Fibre Channel over Ethernet (FCoE) solutions. The following topics are addressed in this chapter:

- [“Fibre Channel over Ethernet” on page 254](#)

Fibre Channel over Ethernet (FCoE) allows Fibre Channel traffic to be transported over Ethernet links. This provides an evolutionary approach toward network consolidation, allowing Fibre Channel equipment and tools to be retained, while leveraging cheap, ubiquitous Ethernet networks for growth.

- [“Converged Enhanced Ethernet” on page 256](#)

Converged Enhanced Ethernet (CEE) refers to a set of IEEE standards developed primarily to enable FCoE, requiring enhancing the existing Ethernet standards to make them lossless on a per-priority traffic basis, and providing a mechanism to carry converged (LAN/SAN/IPC) traffic on a single physical link. CEE features can also be utilized in traditional LAN (non-FCoE) networks to provide lossless guarantees on a per-priority basis, and to provide efficient bandwidth allocation.

- [“FCoE Initialization Protocol Snooping” on page 259](#)

Using FCoE Initialization Protocol (FIP) snooping, the G8264CS examines the FIP frames exchanged between ENodes and FCoE Forwarders (FCFs). This information is used to dynamically determine the ACLs required to block certain types of undesired or unvalidated traffic on FCoE links.

- [“Priority-Based Flow Control” on page 264](#)

Priority-Based Flow Control (PFC) extends 802.3x standard flow control to allow the switch to pause traffic based on the 802.1p priority value in each packet’s VLAN tag. PFC is vital for FCoE environments, where SAN traffic must remain lossless and must be paused during congestion, while LAN traffic on the same links is delivered with “best effort” characteristics.

- [“Enhanced Transmission Selection” on page 268](#)

Enhanced Transmission Selection (ETS) provides a method for allocating link bandwidth based on the 802.1p priority value in each packet’s VLAN tag. Using ETS, different types of traffic (such as LAN, SAN, and management) that are sensitive to different handling criteria can be configured either for specific bandwidth characteristics, low-latency, or best-effort transmission, despite sharing converged links as in an FCoE environment.

- [“Data Center Bridging Capability Exchange” on page 274](#)

Data Center Bridging Capability Exchange Protocol (DCBX) allows neighboring network devices to exchange information about their capabilities. This is used between CEE-capable devices for the purpose of discovering their peers, negotiating peer configurations, and detecting misconfigurations.

Fibre Channel over Ethernet

Fibre Channel over Ethernet (FCoE) is an effort to converge two of the different physical networks in today's data centers. It allows Fibre Channel traffic (such as that commonly used in Storage Area Networks, or SANs) to be transported without loss over 10Gb Ethernet links (typically used for high-speed Local Area Networks, or LANs). This provides an evolutionary approach toward network consolidation, allowing Fibre Channel equipment and tools to be retained, while leveraging cheap, ubiquitous Ethernet networks for growth.

With server virtualization, servers capable of hosting both Fibre Channel and Ethernet applications will provide advantages in server efficiency, particularly as FCoE-enabled network adapters provide consolidated SAN and LAN traffic capabilities.

The RackSwitch G8264CS with Lenovo Networking OS 8.2 software is compliant with the INCITS T11.3, FC-BB-5 FCoE specification, supporting up to 2048 FCoE connections.

Note: The G8264CS supports up to 2048 FCoE login sessions.

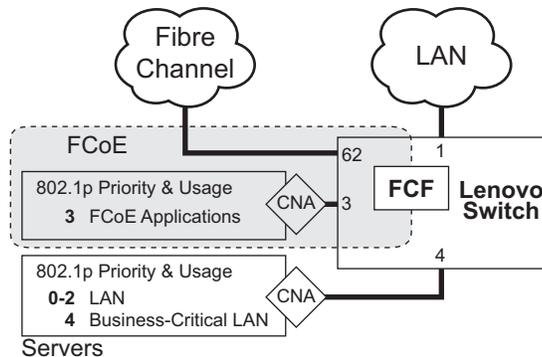

The FCoE Topology

Note: The FCoE topology discussed in this section applies to FCoE Initialization Protocol (FIP) snooping only.

In an end-to-end Fibre Channel network, switches and end devices generally establish trusted, point-to-point links. Fibre Channel switches validate end devices, enforce zoning configurations and device addressing, and prevent certain types of errors and attacks on the network.

In a converged multi-hop FCoE network where Fibre Channel devices are bridged to Ethernet devices, the direct point-to-point QoS capabilities normally provided by the Fibre Channel fabric may be lost in the transition between the different network types. The G8264CS FIP snooping bridge provides a solution to overcome this.

Figure 28. A Mixed Fibre Channel and FCoE Network

In [Figure 28 on page 254](#), the Fibre Channel network is connected to the FCoE network through an FCoE Forwarder (FCF). The FCF acts as a Fibre Channel gateway to and from the FCoE network.

For the FCoE portion of the network, the FCF is connected to the FCoE-enabled G8264CS, which is connected to a server (running Fibre Channel applications) through an FCoE-enabled Converged Network Adapter (CNA) known in Fibre Channel as Ethernet Nodes (ENodes).

Note: The figure also shows a non-FCoE LAN server connected to the G8264CS using a CNA. This allows the LAN server to take advantage of some CEE features that are useful even outside of an FCoE environment.

To block undesired or unvalidated traffic on FCoE links that exists outside the regular Fibre Channel topology, Ethernet ports used in FCoE are configured with Access Control Lists (ACLs) that are narrowly tailored to permit expected FCoE traffic to and from confirmed FCFs and ENodes, and deny all other FCoE or FIP traffic. This ensures that all FCoE traffic to and from the ENode passes through the FCF.

Because manual ACL configuration is an administratively complex task, the G8264CS can automatically and dynamically configure the ACLs required for use with FCoE. Using FCoE Initialization Protocol (FIP) snooping (see [“FCoE Initialization Protocol Snooping” on page 259](#)), the G8264CS examines the FIP frames normally exchanged between the FCF and ENodes to determine information about connected FCoE devices. This information is used to automatically determine the appropriate ACLs required to block certain types of undesired or unvalidated FCoE traffic.

Automatic FCoE-related ACLs are independent from ACLs used for typical Ethernet purposes.

FCoE Requirements

The following are required for implementing FCoE using the RackSwitch G8264CS (G8264CS) with N/OS 8.2 software:

- The G8264CS must be connected to the Fibre Channel network using the switch's built-in Fibre Channel features (see [“Fibre Channel” on page 281](#)) or an external FCF such as another G8264CS or a Cisco Nexus 5000 Series Switch.
- For each G8264CS internal port participating in FCoE, the connected blade server must use the supported FCoE CNA. Emulex Virtual Fabric Adapters (VFAs) for Lenovo Flex System, which includes vNIC support, are currently supported.
- For each G8264CS internal port participating in FCoE, the connected blade server must include the appropriate FCoE licenses installed, as obtained using the Lenovo website Features on Demand (FoD) service. Contact your sales representative for more information on obtaining server feature licenses.
- CEE must be turned on (see [“Turning CEE On or Off” on page 256](#)). When CEE is on, the DCBX, PFC, and ETS features are enabled and configured with default FCoE settings. These features may be reconfigured, but must remain enabled for FCoE to function.
- FIP snooping must be turned on (see [“FCoE Initialization Protocol Snooping” on page 259](#)). When FIP snooping is turned on, the feature is enabled on all ports by default. The administrator can disable FIP snooping on individual ports that do not require FCoE, but FIP snooping must remain enabled on all FCoE ports for FCoE to function.

Converged Enhanced Ethernet

Converged Enhanced Ethernet (CEE) refers to a set of IEEE standards designed to allow different physical networks with different data handling requirements to be converged together, simplifying management, increasing efficiency and utilization, and leveraging legacy investments without sacrificing evolutionary growth.

CEE standards were developed primarily to enable Fibre Channel traffic to be carried over Ethernet networks. This required enhancing the existing Ethernet standards to make them lossless on a per-priority traffic basis, and to provide a mechanism to carry converged (LAN/SAN/IPC) traffic on a single physical link. Although CEE standards were designed with FCoE in mind, they are not limited to FCoE installations. CEE features can be utilized in traditional LAN (non-FCoE) networks to provide lossless guarantees on a per-priority basis, and to provide efficient bandwidth allocation based on application needs.

Turning CEE On or Off

By default on the G8264CS, CEE is turned off. To turn CEE on or off, use the following CLI commands:

```
RS 8264CS(config)# [no] cee enable
```

CAUTION:

Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings on the G8264CS. Read the following material carefully to determine whether you will need to take action to reconfigure expected settings.

It is recommended that you backup your configuration prior to turning CEE on. Viewing the file will allow you to manually re-create the equivalent configuration once CEE is turned on, and will also allow you to recover your prior configuration if you need to turn CEE off.

Effects on Link Layer Discovery Protocol

When CEE is turned on, Link Layer Discovery Protocol (LLDP) is automatically turned on and enabled for receiving and transmitting DCBX information. LLDP cannot be turned off while CEE is turned on.

Effects on 802.1p Quality of Service

While CEE is off (the default), the G8264CS allows 802.1p priority values to be used for Quality of Service (QoS) configuration (see [page 195](#)). 802.1p QoS default settings are shown in [Table 23](#), but can be changed by the administrator.

When CEE is turned on, 802.1p QoS is replaced by ETS (see [“Enhanced Transmission Selection” on page 268](#)). As a result, while CEE is turned on, the 802.1p QoS configuration commands are no longer available on the switch (the menu is restored when CEE is turned off).

In addition, when CEE is turned on, prior 802.1p QoS settings are replaced with new defaults designed for use with ETS priority groups (PGIDs) as shown in [Table 23](#):

Table 23. *CEE Effects on 802.1p Defaults*

802.1p QoS Configuration With CEE Off (default)			ETS Configuration With CEE On		
Priority-	COSq	Weight	Priority	COSq	PGID
0	0	1	0	0	0
1	1	2	1	0	0
2	2	3	2	0	0
3	3	4	3	1	1
4	4	5	4	2	2
5	5	7	5	2	2
6	6	15	6	2	2
7	7	0	7	2	2

When CEE is on, the default ETS configuration also allocates a portion of link bandwidth to each PGID as shown in [Table 24](#):

Table 24. *Default ETS Bandwidth Allocation*

PGID	Typical Use	Bandwidth
0	LAN	10%
1	SAN	50%
2	Latency-sensitive LAN	40%

If the prior, non-CEE configuration used 802.1p priority values for different purposes, or does not expect bandwidth allocation as shown in [Table 24 on page 257](#), when CEE is turned on, have the administrator reconfigure ETS settings as appropriate.

It is recommended that a configuration backup be made prior to turning CEE on or off. Viewing the configuration file will allow the administrator to manually re-create the equivalent configuration under the new CEE mode, and will also allow for the recovery of the prior configuration if necessary.

Effects on Flow Control

When CEE is turned on, standard flow control is disabled on all ports, and in its place, PFC (see [“Priority-Based Flow Control” on page 264](#)) is enabled on all ports for 802.1p priority value 3. This default is chosen because priority value 3 is commonly used to identify FCoE traffic in a CEE environment and must be guaranteed lossless behavior. PFC is disabled for all other priority values.

It is recommend that a configuration backup be made prior to turning CEE on or off. Viewing the configuration file will allow the administrator to manually re-create the equivalent configuration under the new CEE mode, and will also allow for the recovery of the prior configuration if necessary.

When CEE is on, PFC can be enabled only on priority value 3 and one other priority. If flow control is required on additional priorities on any given port, consider using standard flow control on that port, so that regardless of which priority traffic becomes congested, a flow control frame is generated.

FCoE Initialization Protocol Snooping

FCoE Initialization Protocol (FIP) snooping is an FCoE feature. To enforce point-to-point links for FCoE traffic outside the regular Fibre Channel topology, Ethernet ports used in FCoE can be automatically and dynamically configured with Access Control Lists (ACLs).

Using FIP snooping, the G8264CS examines the FIP frames normally exchanged between the FCF and ENodes to determine information about connected FCoE devices. This information is used to create narrowly tailored ACLs that permit expected FCoE traffic to and from confirmed Fibre Channel nodes, and deny all other undesirable FCoE or FIP traffic.

In case of trunk groups, FIP traffic from a particular FCF can be received by any member port on which the FCF was detected.

Port Trunking

Lenovo N/OS 8.2 supports port trunking for FCoE connections. The Link Aggregation (LAG) can be used for separate FCoE traffic, or for Ethernet and FCoE traffic. Ports directly connected to servers cannot be combined in a LAG group.

Uplink ports, connected to the FCF, can be grouped as static or dynamic trunks.

Normal trunk operations such as creating or enabling the trunk and adding or removing member ports can be performed. When a port is added to a trunk group, FCFs previously detected on the port will be deleted. The deleted FCF may be relearned later. However, this may cause flickering in the network traffic. We recommend that you make trunk group changes, if any, prior to live FCoE traffic.

Priority-based Flow Control (PFC) and Data Center Bridging (DCBX) are configured on a per-port basis. Each port in a trunk must have the same ETS, PFC, and DCBX configuration. When a port ceases to be the trunk group member, its configuration does not change.

Note: If the ports chosen to make a LAG or a trunk do not have the same configuration of PFC, ETS, or DCBX, the switch will throw an error.

Global FIP Snooping Settings

By default, the FIP snooping feature is turned off for the G8264CS. The following commands are used to turn the feature on or off:

```
RS 8264CS(config)# [no] fcoe fips enable
```

Note: FIP snooping requires CEE to be turned on (see [“Turning CEE On or Off” on page 256](#)).

When FIP snooping is on, port participation may be configured on a port-by-port basis (see the next sections).

When FIP snooping is off, all FCoE-related ACLs generated by the feature are removed from all switch ports.

FIP snooping configuration must be the same on all member ports in a trunk group. If the configuration of a member port is changed, an error message, similar to the following, will be displayed.

```
"FAIL: Trunk X FIP Snooping port Y and port Z need to have the same fcf mode config"
```

The configuration changes are applied to all member ports in a trunk group.

FIP Snooping for Specific Ports

When FIP snooping is globally turned on (see the previous section), ports may be individually configured for participation in FIP snooping and automatic ACL generation. By default, FIP snooping is enabled for each port. To change the setting for any specific port, use the following CLI commands:

```
RS 8264CS(config)# [no] fcoe fips port <port alias, number, list, or range> enable
```

When FIP snooping is enabled on a port, FCoE-related ACLs will be automatically configured.

When FIP snooping is disabled on a port, all FCoE-related ACLs on the port are removed, and the switch will enforce no FCoE-related rules for traffic on the port.

Port FCF and ENode Detection

When FIP snooping is enabled on a port, the port is placed in FCF auto-detect mode by default. In this mode, the port assumes connection to an ENode unless FIP packets show the port is connected to an FCF.

Ports can also be specifically configured as to whether automatic FCF detection will be used, or whether the port is connected to an FCF or ENode:

```
RS 8264CS(config)# fcoe fips port <port alias, number, list, or range> fcf-mode {auto|on|off}
```

When FCF mode is on, the port is assumed to be connected to a trusted FCF, and only ACLs appropriate to FCFs will be installed on the port. When off, the port is assumed to be connected to an ENode, and only ACLs appropriate to ENodes will be installed. When the mode is changed (either through manual configuration or as a result of automatic detection), the appropriate ACLs are automatically added, removed, or changed to reflect the new FCF or ENode connection.

FCoE Connection Timeout

FCoE-related ACLs are added, changed, and removed as FCoE device connection and disconnection are discovered. In addition, the administrator can enable or disable automatic removal of ACLs for FCFs and other FCoE connections that timeout (fail or are disconnected) without FIP notification.

By default, automatic removal of ACLs upon timeout is enabled. To change this function, use the following CLI command:

```
RS 8264CS(config)# [no] fcoe fips timeout-acl
```

FCoE ACL Rules

When FIP Snooping is enabled on a port, the switch automatically installs the appropriate ACLs to enforce the following rules for FCoE traffic:

- Ensure that FIP frames from ENodes may only be addressed to FCFs.
- Flag important FIP packets for switch processing.
- Ensure no end device uses an FCF MAC address as its source.
- Each FCoE port is assumed to be connected to an ENode and include ENode-specific ACLs installed, until the port is either detected or configured to be connected to an FCF.
- Ports that are configured to have FIP snooping disabled will not have any FIP or FCoE related ACLs installed.
- Prevent transmission of all FCoE frames from an ENode prior to its successful completion of login (FLOGI) to the FCF.
- After successful completion of FLOGI, ensure that the ENode uses only those FCoE source addresses assigned to it by FCF.
- After successful completion of FLOGI, ensure that all ENode FCoE source addresses originate from or are destined to the appropriate ENode port.
- After successful completion of each FLOGI, ensure that FCoE frames may only be addressed to the FCFs that accept them.

Initially, a basic set of FCoE-related ACLs will be installed on all ports where FIP snooping is enabled. As the switch encounters FIP frames and learns about FCFs and ENodes that are attached or disconnect, ACLs are dynamically installed or expanded to provide appropriate security.

When an FCoE connection logs out, or times out (if ACL timeout is enabled), the related ACLs will be automatically removed.

FCoE-related ACLs are independent of manually configured ACLs used for regular Ethernet purposes (see [“Access Control Lists” on page 105](#)). FCoE ACLs generally have a higher priority over standard ACLs, and do not inhibit non-FCoE and non-FIP traffic.

FCoE VLANs

FCoE packets to any FCF will be confined to the VLAN advertised by the FCF (typically VLAN 1002). The appropriate VLAN must be configured on the switch with member FCF ports and must be supported by the participating CNAs. The switch will then automatically add ENode ports to the appropriate VLAN and enable tagging on those ports.

Note: If using an Emulex CNA, you must create the FCoE VLAN add the ENode and FCF ports to that VLAN using the CLI.

Viewing FIP Snooping Information

ACLs automatically generated under FIP snooping are independent of regular, manually configure ACLs, and are not listed with regular ACLs in switch information and statistics output. Instead, FCoE ACLs are shown using the following CLI commands:

```
RS 8264CS# show fcoe fips information (Show all FIP-related information)
RS 8264CS# show fcoe fips port <ports> information (Show FIP info for a selected port)
```

For example:

```
RS 8264CS# show fcoe fips port 21 information

FIP Snooping on port 21:
This port has been configured to automatically detect FCF.
It has currently detected to have 0 FCF connecting to it.

FIPS ACLs configured on this port:
SMAC 00:05:73:ce:96:67, action deny.
DMAC 00:05:73:ce:96:67, ethertype 0x8914, action permit.
SMAC 0e:fc:00:44:04:04, DMAC 00:05:73:ce:96:67, ethertype 0x8906, vlan
1002, action permit.
DMAC 01:10:18:01:00:01, Ethertype 0x8914, action permit.
DMAC 01:10:18:01:00:02, Ethertype 0x8914, action permit.
Ethertype 0x8914, action deny.
Ethertype 0x8906, action deny.
SMAC 0e:fc:00:00:00:00, SMAC mask ff:ff:ff:00:00:00, action deny.
```

For each ACL, the required traffic criteria are listed, along with the action taken (permit or deny) for matching traffic. ACLs are listed in order of precedence and evaluated in the order shown.

The administrator can also view other FCoE information:

```
RS 8264CS# show fcoe fips fcf (Show all detected FCFs)
RS 8264CS# show fcoe fips fcoe (Show all FCoE connections)
```

Operational Commands

The administrator may use the operational commands to delete FIP-related entries from the switch.

To delete a specific FCF entry and all associated ACLs from the switch, use the following command:

```
RS 8264CS# no fcoe fips fcf <FCF MAC address> [<VLAN number>]
```

FIP Snooping Configuration

In this example, as shown in [Figure 28 on page 254](#), FCoE devices are connected to port 62 for the FCF device, and port 3 for an ENode. FIP snooping can be configured on these ports using the following ISCLI commands:

1. Enable VLAN tagging on the FCoE ports:

```
RS 8264CS(config)# interface port 3,62 (Select FCoE ports)
RS 8264CS(config-if)# switchport mode trunk (Enable VLAN tagging)
RS 8264CS(config-if)# exit (Exit port configuration mode)
```

2. Place FCoE ports into a VLAN supported by the FCF and CNAs (typically VLAN 1002):

```
RS 8264CS(config)# vlan 1002 (Select a VLAN)
RS 8264CS(config-vlan)# exit (Exit VLAN configuration mode)
RS 8264CS(config)# interface port 3,62 (Add FCoE ports to the VLAN)
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 1002
RS 8264CS(config-if)# exit
```

3. Turn CEE on.

```
RS 8264CS(config)# cee enable
```

Note: Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings and menus (see [“Turning CEE On or Off” on page 256](#)).

4. Turn global FIP snooping on:

```
RS 8264CS(config)# fcoe fips enable
```

5. Enable FIP snooping on FCoE ports, and set the desired FCF mode:

```
RS 8264CS(config)# fcoe fips port 2 enable (Enable FIPS on port 2)
RS 8264CS(config)# fcoe fips port 2 fcf-mode on (Set as FCF connection)
RS 8264CS(config)# fcoe fips port 3 enable (Enable FIPS on port 3)
RS 8264CS(config)# fcoe fips port 3 fcf-mode off (Set as ENode connection)
```

Note: By default, FIP snooping is enabled on all ports and the FCF mode set for automatic detection. The configuration in this step is unnecessary, if default settings have not been changed, and is shown merely as a manual configuration example.

6. Save the configuration.

Priority-Based Flow Control

Priority-based Flow Control (PFC) is defined in IEEE 802.1Qbb. PFC extends the IEEE 802.3x standard flow control mechanism. Under standard flow control, when a port becomes busy, the switch manages congestion by pausing all the traffic on the port, regardless of the traffic type. PFC provides more granular flow control, allowing the switch to pause specified types of traffic on the port, while other traffic on the port continues.

PFC pauses traffic based on 802.1p priority values in the VLAN tag. The administrator can assign different priority values to different types of traffic and then enable PFC for up to two specific priority values: priority value 3, and one other. The configuration can be applied globally for all ports on the switch. Then, when traffic congestion occurs on a port (caused when ingress traffic exceeds internal buffer thresholds), only traffic with priority values where PFC is enabled is paused. Traffic with priority values where PFC is disabled proceeds without interruption but may be subject to loss if port ingress buffers become full.

Although PFC is useful for a variety of applications, it is required for FCoE implementation where storage (SAN) and networking (LAN) traffic are converged on the same Ethernet links. Typical LAN traffic tolerates Ethernet packet loss that can occur from congestion or other factors, but SAN traffic must be lossless and requires flow control.

For FCoE, standard flow control would pause both SAN and LAN traffic during congestion. While this approach would limit SAN traffic loss, it could degrade the performance of some LAN applications that expect to handle congestion by dropping traffic. PFC resolves these FCoE flow control issues. Different types of SAN and LAN traffic can be assigned different IEEE 802.1p priority values. PFC can then be enabled for priority values that represent SAN and LAN traffic that must be paused during congestion, and disabled for priority values that represent LAN traffic that is more loss-tolerant.

PFC requires CEE to be turned on ([“Turning CEE On or Off” on page 256](#)). When CEE is turned on, PFC is enabled on priority value 3 by default. Optionally, the administrator can also enable PFC on one other priority value, providing lossless handling for another traffic type, such as for a business-critical LAN application.

Note: For any given port, only one flow control method can be implemented at any given time: either PFC or standard IEEE 802.3x flow control.

Global Configuration

PFC requires CEE to be turned on ([“Turning CEE On or Off” on page 256](#)). When CEE is turned on, standard flow control is disabled on all ports, and PFC is enabled on all ports for 802.1p priority value 3. While CEE is turned on, PFC cannot be disabled for priority value 3. This default is chosen because priority value 3 is commonly used to identify FCoE traffic in a CEE environment and must be guaranteed lossless behavior. PFC is disabled for all other priority values by default, but can be enabled for one additional priority value.

- Global PFC configuration is preferable in networks that implement end-to-end CEE devices. For example, if all ports are involved with FCoE and can use the same SAN and LAN priority value configuration with the same PFC settings, global configuration is easy and efficient.

- Global PFC configuration can also be used in some mixed environments where traffic with PFC-enabled priority values occurs only on ports connected to CEE devices, and not on any ports connected to non-CEE devices. In such cases, PFC can be configured globally on specific priority values even though not all ports make use them.
- PFC is not restricted to CEE and FCoE networks. In any LAN where traffic is separated into different priorities, PFC can be enabled on priority values for loss-sensitive traffic.
- If you want to enable PFC on a priority, do one of the following:
 - Create a separate PG (separate COS Q) (or)
 - Move the priority to the existing PG in which PFC is turned on.Option 1 will be more preferred as you have separate Q and separate ETS configuration.
- When configuring ETS and PFC on the switch, perform ETS configuration before performing PFC configuration.
- If two priorities are enabled on a port, the switch sends PFC frames for both priorities, even if only traffic tagged with one of the priorities is being received on that port.

Note: When using global PFC configuration in conjunction with the ETS feature (see [“Enhanced Transmission Selection” on page 268](#)), ensure that only pause-tolerant traffic (such as lossless FCoE traffic) is assigned priority values where PFC is enabled. Pausing other types of traffic can have adverse effects on LAN applications that expect uninterrupted traffic flow and tolerate dropping packets during congestion.

PFC Configuration Example

Note: DCBX may be configured to permit sharing or learning PFC configuration with or from external devices. This example assumes that PFC configuration is being performed manually. See [“Data Center Bridging Capability Exchange” on page 274](#) for more information on DCBX. Even if the G8264CS learns the PFC configuration from a DCBX peer, the PFC configuration must be performed manually.

This example is consistent with the network shown in [Figure 28 on page 254](#). In this example, the following topology is used.

Table 25. *Port-Based PFC Configuration*

Switch Port	802.1p Priority	Usage	PFC Setting
1	0-2	LAN	Disabled
	3	(not used)	Enabled
	4	Business-critical LAN	Enabled
	others	(not used)	Disabled
3	3	FCoE	Enabled
	others	(not used)	Disabled
4	0-2	LAN	Disabled
	3	(not used)	Enabled
	4	Business-critical LAN	Enabled
	others	(not used)	Disabled
62	3	Fibre Channel network	Enabled
	others	(not used)	Disabled

In this example, PFC is to facilitate lossless traffic handling for FCoE (priority value 3) and a business-critical LAN application (priority value 4).

Assuming that CEE is off (the G8264CS default), the example topology shown in [Table 25](#) can be configured using the following commands:

1. Turn CEE on.

```
RS 8264CS(config)# cee enable
```

Note: Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings and menus (see [“Turning CEE On or Off” on page 256](#)).

2. Enable PFC for the FCoE traffic.

Note: PFC is enabled on priority 3 by default. If using the defaults, the manual configuration commands shown in this step are not necessary.

```
RS 8264CS(config)# cee global pfc priority 3 enable(Enable on FCoE priority)
RS 8264CS(config)# cee global pfc priority 3 description "FCoE"
(Optional description)
```

3. Enable PFC for the business-critical LAN application:

```
RS 8264CS(config)# cee global pfc priority 4 enable(Enable on LAN priority)
RS 8264CS(config)# cee global pfc priority 4 description "Critical LAN"
(Optional description)
```

4. Save the configuration.

In the assignment model shown in [Figure 29 on page 268](#), priority values 0 through 2 are assigned for regular Ethernet traffic, which has “best effort” transport characteristics.

Because CEE and ETS features are generally associated with FCoE, Priority 3 is typically used to identify FCoE (SAN) traffic.

Priorities 4-7 are typically used for latency sensitive traffic and other important business applications. For example, priority 4 and 5 are often used for video and voice applications such as IPTV, Video on Demand (VoD), and Voice over IP (VoIP). Priority 6 and 7 are often used for traffic characterized with a “must get there” requirement, with priority 7 used for network control which requires guaranteed delivery to support configuration and maintenance of the network infrastructure.

Note: The default assignment of 802.1p priority values on the G8264CS changes depending on whether CEE is on or off. See [“Turning CEE On or Off” on page 256](#) for details.

Priority Groups

For ETS use, each 801.2p priority value is assigned to a priority group which can then be allocated a specific portion of available link bandwidth. To configure a priority group, the following is required:

- CEE must be turned on ([“Turning CEE On or Off” on page 256](#)) for the ETS feature to function.
- A priority group must be assigned a priority group ID (PGID), one or more 802.1p priority values, and allocated link bandwidth greater than 9%.

PGID

Each priority group is identified with number (0 through 7, and 15) known as the PGID.

PGID 0 through 7 may each be assigned a portion of the switch’s available bandwidth.

PGID 8 through 14 are reserved as per the 802.1Qaz ETS standard.

PGID 15 is a strict priority group. It is generally used for critical traffic, such as network management. Any traffic with priority values assigned to PGID 15 is permitted as much bandwidth as required, up to the maximum available on the switch. After serving PGID 15, any remaining link bandwidth is shared among the other groups, divided according to the configured bandwidth allocation settings.

Make sure all 802.1p priority values assigned to a particular PGID have similar traffic handling requirements. For example, PFC-enabled traffic must not be grouped with non-PFC traffic. Also, traffic of the same general type must be assigned to the same PGID. Splitting one type of traffic into multiple 802.1p priorities, and then assigning those priorities to different PGIDs may result in unexpected network behavior.

Each 802.1p priority value may be assigned to only one PGID. However, each PGID may include multiple priority values. Up to eight PGIDs may be configured at any given time. However, no more than three ETS Priority Groups may include priority values for which PFC is disabled.

Assigning Priority Values to a Priority Group

Each priority group may be configured from its corresponding ETS Priority Group, available using the following command:

```
RS 8264CS(config)# cee global ets priority-group pgid <group number (0-7, or 15)>
priority <priority list>
```

where *priority list* is one or more 802.1p priority values (with each separated by a comma). For example, to assign priority values 0 through 2:

```
RS 8264CS(config)# cee global ets priority-group pgid <group number (0-7, or 15)>
priority 0,1,2
```

Note: Within any specific PGID, the PFC settings (see [“Priority-Based Flow Control” on page 264](#)) must be the same (enabled or disabled) for all priority values within the group. PFC can be enabled only on priority value 3 and one other priority. Also, no more than three ETS Priority Groups may include priority values for which PFC is disabled.

When assigning priority values to a PGID, the specified priority value will be automatically removed from its old group and assigned to the new group when the configuration is applied.

Each priority value must be assigned to a PGID. Priority values may not be deleted or unassigned. To remove a priority value from a PGID, it must be moved to another PGID.

For PGIDs 0 through 7, bandwidth allocation can also be configured through the ETS Priority Group menu. See for [“Allocating Bandwidth” on page 270](#) for details.

Deleting a Priority Group

A priority group is automatically deleted when it contains no associated priority values, and its bandwidth allocation is set to 0%.

Note: The total bandwidth allocated to PGID 0 through 7 must equal exactly 100%. Reducing the bandwidth allocation of any group will require increasing the allocation to one or more of the other groups (see [“Allocating Bandwidth” on page 270](#)).

Allocating Bandwidth

Allocated Bandwidth for PGID 0 Through 7

The administrator may allocate a portion of the switch’s available bandwidth to PGIDs 0 through 7. Available bandwidth is defined as the amount of link bandwidth that remains after priorities within PGID 15 are serviced (see [“Unlimited Bandwidth for PGID 15” on page 271](#)), and assuming that all PGIDs are fully subscribed. If any PGID does not fully consume its allocated bandwidth, the unused portion is made available to the other priority groups.

Priority group bandwidth allocation can be configured using the following command:

```
RS 8264CS(config)# cee global ets priority-group pgid <priority group number>
bandwidth <bandwidth allocation> pgid
```

where *bandwidth allocation* represents the percentage of link bandwidth, specified as a number between 10 and 100, in 1% increments, or 0.

The following bandwidth allocation rules apply:

- Bandwidth allocation must be 0% for any PGID that has no assigned 802.1p priority values.
- Any PGID assigned one or more priority values must have a bandwidth allocation greater than 9%.
- Total bandwidth allocation for groups 0 through 7 must equal exactly 100%. Increasing or reducing the bandwidth allocation of any PGID also requires adjusting the allocation of other PGIDs to compensate.

If these conditions are not met, the switch will report an error when applying the configuration.

Note: Actual bandwidth used by any specific PGID may vary from configured values by up to 10% of the available bandwidth in accordance with 802.1Qaz ETS standard. For example, a setting of 10% may be served anywhere from 0% to 20% of the available bandwidth at any given time.

Unlimited Bandwidth for PGID 15

PGID 15 is permitted unlimited bandwidth and is generally intended for critical traffic (such as switch management). Traffic in this group is given highest priority and is served before the traffic in any other priority group.

If PGID 15 has low traffic levels, most of the switch's bandwidth will be available to serve priority groups 0 through 7. However, if PGID 15 consumes a larger part of the switch's total bandwidth, the amount available to the other groups is reduced.

Note: Consider traffic load when assigning priority values to PGID 15. Heavy traffic in this group may restrict the bandwidth available to other groups.

Configuring ETS

Consider an example consistent with that used for port-based PFC configuration (on [page 266](#)):

Table 26. *ETS Configuration*

Priority	Usage	PGID	Bandwidth
0	LAN (best effort delivery)	2	10%
1	LAN (best effort delivery)		
2	LAN (best effort delivery)		
3	SAN (Fibre Channel over Ethernet, with PFC)	3	20%
4	Business Critical LAN (lossless Ethernet, with PFC)	4	30%
5	Latency-sensitive LAN	5	40%
6	Latency-sensitive LAN		
7	Network Management (strict)	15	unlimited

The example shown in [Table 26](#) is only slightly different than the default configuration shown in [Figure 29 on page 268](#). In this example, latency-sensitive LAN traffic (802.1p priority 5 through 6) are moved from priority group 4 to priority group 5. This leaves Business Critical LAN traffic (802.1p priority 4) in priority group 4 by itself. Also, a new group for network management traffic has been assigned. Finally, the bandwidth allocation for priority groups 1, 2, and 3 are revised.

Note: DCBX may be configured to permit sharing or learning PFC configuration with or from external devices. This example assumes that PFC configuration is being performed manually. See [“Data Center Bridging Capability Exchange” on page 274](#) for more information on DCBX.

This example can be configured using the following commands:

1. Turn CEE on.

```
RS 8264CS(config)# cee enable
```

Note: Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings and menus (see [“Turning CEE On or Off” on page 256](#)).

2. Configure each allocated priority group with a description (optional), list of 802.1p priority values, and bandwidth allocation:

```
RS 8264CS(config)# cee global ets priority-group pgid 2 priority 0,1,2
                                     (Select a group for regular LAN, and
                                     set for 802.1p priorities 0, 1, and 2)
RS 8264CS(config)# cee global ets priority-group pgid 2 description
"Regular LAN"
                                     (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 3 priority 3
                                     (Select a group for SAN traffic, and
                                     set for 802.1p priority 3)
RS 8264CS(config)# cee global ets priority-group pgid 3 description "SAN"
                                     (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 4 priority 4
                                     (Select a group for latency traffic,
                                     and set for 802.1p priority 4)
RS 8264CS(config)# cee global ets priority-group pgid 4 description
"Biz-Critical LAN"
                                     (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 5 priority 5,6 pgid
4 bandwidth 20 pgid 5 bandwidth 20
```

3. Configure the strict priority group with a description (optional) and a list of 802.1p priority values:

```
RS 8264CS(config)# cee global ets priority-group pgid 15 priority 7
                                     (Select a group for strict traffic, and
                                     Set 802.1p priority 7)
RS 8264CS(config)# cee global ets priority-group pgid 15 description
"Network Management"
                                     (Set a group description—optional)
```

Note: Priority group 15 is permitted unlimited bandwidth. As such, the commands for priority group 15 do not include bandwidth allocation.

4. Save the configuration.

To view the configuration, use the following command:

```
RS 8264CS(config)# show cee global ets

Current ETS Configuration:
Number of COSq: 8

Current Mapping of 802.1p Priority to Priority Groups:

Priority  PGID  COSq
-----  ----  ----
    0      2     2
    1      2     2
    2      2     2
    3      3     3
    4      4     4
    5      5     4
    6      5     4
    7     15     7

Current Bandwidth Allocation to Priority Groups:

PGID  PG%  Description
-----  ---  -----
    2   10  Regular LAN
    3   20  SAN
    4   30  Biz-Critical LAN
    5   40  Latency-sensitive LAN
   15    -  Network Management
```

Data Center Bridging Capability Exchange

Data Center Bridging Capability Exchange (DCBX) protocol is a vital element of CEE. DCBX allows peer CEE devices to exchange information about their advanced capabilities. Using DCBX, neighboring network devices discover their peers, negotiate peer configurations, and detect misconfigurations.

DCBX provides two main functions on the G8264CS:

- Peer information exchange
The switch uses DCBX to exchange information with connected CEE devices. For normal operation of any FCoE implementation on the G8264CS, DCBX must remain enabled on all ports participating in FCoE.
- Peer configuration negotiation
DCBX also allows CEE devices to negotiate with each other for the purpose of automatically configuring advanced CEE features such as PFC, ETS, and (for some CNAs) FIP. The administrator can determine which CEE feature settings on the switch are communicated to and matched by CEE neighbors, and also which CEE feature settings on the switch may be configured by neighbor requirements.

The DCBX feature requires CEE to be turned on (see [“Turning CEE On or Off” on page 256](#)).

DCBX Settings

When CEE is turned on, DCBX is enabled for peer information exchange on all ports. For configuration negotiation, the following default settings are configured:

- Application Protocol: FCoE and FIP snooping is set for traffic with 802.1p priority 3
- PFC: Enabled on 802.1p priority 3
- ETS
 - Priority group 2 includes priority values 0 through 2, with bandwidth allocation of 10%
 - Priority group 3 includes priority value 3, with bandwidth allocation of 50%
 - Priority group 4 includes priority values 4 through 7, with bandwidth allocation of 40%

Enabling and Disabling DCBX

When CEE is turned on, DCBX can be enabled and disabled on a per-port basis, using the following commands:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx enable
```

When DCBX is enabled on a port, Link Layer Detection Protocol (LLDP) is used to exchange DCBX parameters between CEE peers. Also, the interval for LLDP transmission time is set to one second for the first five initial LLDP transmissions,

after which it is returned to the administratively configured value. The minimum delay between consecutive LLDP frames is also set to one second as a DCBX default.

Peer Configuration Negotiation

CEE peer configuration negotiation can be set on a per-port basis for a number of CEE features. For each supported feature, the administrator can configure two independent flags:

- The `advertise` flag

When this flag is set for a particular feature, the switch settings will be transmitted to the remote CEE peer. If the peer is capable of the feature, and willing to accept the G8264CS settings, it will be automatically reconfigured to match the switch.

- The `willing` flag

Set this flag when required by the remote CEE peer for a particular feature as part of DCBX signaling and support. Although some devices may also expect this flag to indicate that the switch will accept overrides on feature settings, the G8264CS retains its configured settings. As a result, the administrator must configure the feature settings on the switch to match those expected by the remote CEE peer.

These flags are available for the following CEE features:

- Application Protocol

DCBX exchanges information regarding FCoE and FIP snooping, including the 802.1p priority value used for FCoE traffic. The `advertise` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx app_proto  
advertise
```

The `willing` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx app_proto  
willing
```

- PFC

DCBX exchanges information regarding whether PFC is enabled or disabled on the port. The `advertise` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx pfc advertise
```

The `willing` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx pfc willing
```

- ETS
DCBX exchanges information regarding ETS priority groups, including their 802.1p priority members and bandwidth allocation percentages. The `advertise` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx ets advertise
```

The `willing` flag is set or reset using the following command:

```
RS 8264CS(config)# [no] cee port <port alias or number> dcbx ets willing
```

Configuring DCBX

Consider an example consistent [Figure 28 on page 254](#) and used with the previous FCoE examples in this chapter:

- FCoE is used on ports 62 and 3.
- CEE features are also used with LANs on ports 1 and 4.
- All other ports are disabled or are connected to regular (non-CEE) LAN devices.

In this example, the G8264CS acts as the central point for CEE configuration. FCoE-related ports will be configured for advertising CEE capabilities, but not to accept external configuration. Other LAN ports that use CEE features will also be configured to advertise feature settings to remote peers, but not to accept external configuration. DCBX will be disabled on all non-CEE ports.

This example can be configured using the following commands:

1. Turn CEE on.

```
RS 8264CS(config)# cee enable
```

Note: Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings and menus (see [“Turning CEE On or Off” on page 256](#)).

2. Enable desired DCBX configuration negotiation on FCoE ports:

```
RS 8264CS(config)# cee port 62 dcbx enable
RS 8264CS(config)# cee port 62 dcbx app_proto advertise
RS 8264CS(config)# cee port 62 dcbx ets advertise
RS 8264CS(config)# cee port 62 dcbx pfc advertise

RS 8264CS(config)# cee port 3 dcbx enable
RS 8264CS(config)# cee port 3 dcbx app_proto advertise
RS 8264CS(config)# cee port 3 dcbx ets advertise
RS 8264CS(config)# cee port 3 dcbx pfc advertise
```

3. Enable desired DCBX advertisements on other CEE ports:

```
RS 8264CS(config)# cee port 1 dcbx enable
RS 8264CS(config)# cee port 1 dcbx app_proto advertise
RS 8264CS(config)# cee port 1 dcbx ets advertise
RS 8264CS(config)# cee port 1 dcbx pfc advertise

RS 8264CS(config)# cee port 4 dcbx enable
RS 8264CS(config)# cee port 4 dcbx app_proto advertise
RS 8264CS(config)# cee port 4 dcbx ets advertise
RS 8264CS(config)# cee port 4 dcbx pfc advertise
```

4. Disable DCBX for each non-CEE port as appropriate:

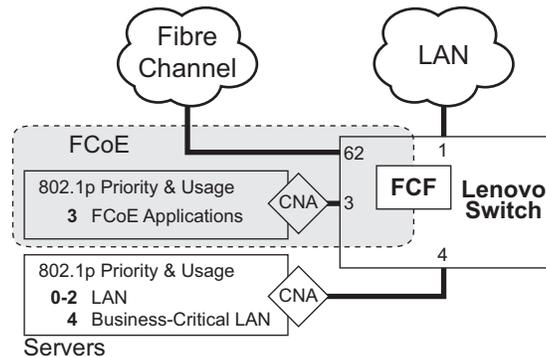

```
RS 8264CS(config)# no cee port 2,5-61,63-64 dcbx enable
```

5. Save the configuration.

FCoE Example Configuration

The following example collects the various components from previous sections of this chapter.

Figure 30. A Mixed Fibre Channel and FCoE Network

In [Figure 30 on page 278](#), a Fibre Channel network is connected to the G8264CS on port 62. The FCoE-enabled G8264CS is connected to a server (ENode) through an FCoE-enabled CNA on port 3. The G8264CS acts as an FCF, bridging the CNA to the Fibre Channel network.

1. Configure FCoE ports as trunk ports and make them part of FCoE Vlan for FCoE traffic and Native Vlan 1 for FIP negotiation.:

```
RS 8264CS(config)# interface port 3 (Select FCoE ports)
RS 8264CS(config-if)# switchport mode trunk (Enable VLAN tagging)
RS 8264CS(config-if)# switchport mode trunk allowed vlan 1,1002
RS 8264CS(config-if)# exit (Exit port configuration mode)
```

2. Place FCoE ports into a VLAN supported by the FCF and CNAs (typically VLAN 1002):

```
RS 8264CS(config)# vlan 1002 (Select a VLAN)
RS 8264CS(config-vlan)# member 3 (Add FCoE ports to the VLAN)
RS 8264CS(config-vlan)# enable (Enable the VLAN)
RS 8264CS(config-vlan)# exit (Exit VLAN configuration mode)
```

Note: Placing ports into the VLAN ([Step 2](#)) *after* tagging is enabled helps to ensure that their port VLAN ID (PVID) is not accidentally changed.

3. Turn CEE on.

```
RS 8264CS(config)# cee enable
```

Note: Turning CEE on will automatically change some 802.1p QoS and 802.3x standard flow control settings and menus (see [“Turning CEE On or Off” on page 256](#)).

4. Turn global FIP snooping on:

```
RS 8264CS(config)# fcoe fips enable
```

5. Disable FIP snooping on all non-FCoE external ports:

```
RS 8264CS(config)# no fcoe fips port 1-2,4-64 enable
```

6. Enable FIP snooping on FCoE ports, and set the desired FCF mode:

```
RS 8264CS(config)# fcoe fips port 3 enable
RS 8264CS(config)# fcoe fips port 3 fcf-mode off (Set as ENode connection)
```

Note: By default, FIP snooping is enabled on all ports and the FCF mode set for automatic detection. The configuration in this step is unnecessary if default settings have not been changed, and is shown merely as a manual configuration example.

7. Enable PFC for the FCoE traffic.

Note: PFC is enabled on priority 3 by default. If using the defaults, the manual configuration commands shown in this step are not necessary.

```
RS 8264CS(config)# cee port 3 pfc priority 3 enable (FCoE priority)
RS 8264CS(config)# cee port 3 pfc priority 3 description "FCoE" (Optional)
```

8. Enable PFC for the business-critical LAN application:

```
RS 8264CS(config)# cee port 4 pfc priority 4 enable (LAN priority)
RS 8264CS(config)# cee port 4 pfc priority 4 description "Critical LAN"
RS 8264CS(config)# cee port 1 pfc priority 4 enable (LAN priority)
RS 8264CS(config)# cee port 1 pfc priority 4 description "Critical LAN"
```

9. Configure each allocated priority group with a description (optional), list of 802.1p priority values, and bandwidth allocation:

```
RS 8264CS(config)# cee global ets priority-group pgid 0 priority 0,1,2
                        (Select a group for regular LAN, and
                        set for 802.1p priorities 0, 1, and 2)
RS 8264CS(config)# cee global ets priority-group pgid 0 description
"Regular LAN"
                        (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 1 priority 3
                        (Select a group for SAN traffic, and
                        set for 802.1p priority 3)
RS 8264CS(config)# cee global ets priority-group pgid 1 description "SAN"
                        (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 2 priority 4
                        (Select a group for latency traffic,
                        and set for 802.1p priority 4)
RS 8264CS(config)# cee global ets priority-group pgid 2 description
"Critical"
                        (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 3 description
"Latency-Sensitive LAN"
                        (Set a group description—optional)
RS 8264CS(config)# cee global ets priority-group pgid 3 priority 5,6 pgid
0 bandwidth 10 pgid 1 bandwidth 20 pgid 2 bandwidth 30 pgid 3 bandwidth
40
                        (Configure link bandwidth restriction)
```

10. Configure the strict priority group with a description (optional) and a list of 802.1p priority values:

```
RS 8264CS(config)# cee global ets priority-group pgid 15 priority 7
RS 8264CS(config)# cee global ets priority-group pgid 15 description
"Network Management"
```

Note: Priority group 15 is permitted unlimited bandwidth. As such, the commands for priority group 15 do not include bandwidth allocation.

11. Enable desired DCBX configuration negotiation on FCoE ports:

```
RS 8264CS(config)# cee port 3 dcbx enable
RS 8264CS(config)# cee port 3 dcbx app_proto advertise
RS 8264CS(config)# cee port 3 dcbx ets advertise
RS 8264CS(config)# cee port 3 dcbx pfc advertise
```

12. Enable desired DCBX advertisements on other CEE ports:

```
RS 8264CS(config)# cee port 1 dcbx enable
RS 8264CS(config)# cee port 1 dcbx app_proto advertise
RS 8264CS(config)# cee port 1 dcbx ets advertise
RS 8264CS(config)# cee port 1 dcbx pfc advertise

RS 8264CS(config)# cee port 4 dcbx enable
RS 8264CS(config)# cee port 4 dcbx app_proto advertise
RS 8264CS(config)# cee port 4 dcbx ets advertise
RS 8264CS(config)# cee port 4 dcbx pfc advertise
```

13. Disable DCBX for each non-CEE port as appropriate:

```
RS 8264CS(config)# no cee port 2,5-61,63-64 dcbx enable
```

14. Configure the Fibre Channel network:

```
RS 8264CS(config)# system port 61-62 type fc
RS 8264CS(config)# interface fc ext22
RS 8264CS(config-if)# switchport trunk allowed vlan 1,1002
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 1002
RS 8264CS(config-vlan)# npv enable
RS 8264CS(config-vlan)# npv traffic-map external-interface 62
RS 8264CS(config-vlan)# exit
```

Note: The Fibre Channel network is configured as an NPV gateway as described in [“NPV Gateway” on page 283](#). Although VLAN properties for Fibre Channel and FCoE can be configured together, the additional Fibre Channel elements for this configuration are included at the end of this example in order to focus on the FCoE steps.

15. Save the configuration.

Chapter 18. Fibre Channel

This chapter describes how to configure the G8264CS for use with Fibre Channel networks.

Ethernet vs. Fibre Channel

As a converged switch, the RackSwitch G8264CS provides simultaneous support of Ethernet and Fibre Channel networks.

Ethernet is ubiquitous in modern networks. It is generally quick, easy, and inexpensive to implement. Ethernet is also flexible and dynamic by nature. Devices join and leave a well-designed Ethernet network with little impact beyond their individual function. Because flux is the norm, Ethernet is classified as a "best effort" delivery protocol. This means that some loss of packets is acceptable, and that with multiple routes often available, packets in a stream may arrive at their destination out of sequence. Ethernet devices are expected to re-request and resend lost packets, and reassemble data in the proper order at the destination.

The Fibre Channel protocol adheres to a very different philosophy. Fibre Channel is most popular in storage networks end-to-end stability, reliability, and security are emphasized in favor over low cost and dynamic scalability. In Fibre Channel networks, the connecting ports must be fully authorized to communicate with their well-defined neighbors. Bandwidth for properly connected devices is tuned to avoid loss due to congestion. Also, routes for traffic are converged in advance, ensuring that only one route is used by any given traffic stream so that packets arrive in their expected sequence.

Ethernet and Fibre Channel networks are coming into contact with each other more frequently in modern networks. In some cases, legacy Fibre Channel devices are connected via Ethernet networks using Converged Enhanced Ethernet (CEE), a collection of recent Ethernet features designed to satisfy Fibre Channel delivery expectations. Although not the focus of this chapter, the G8264CS supports CEE and Fibre Channel over Ethernet (FCoE). For details, see [“FCoE and CEE” on page 253](#).

Another approach is to use converged switches such as the G8264CS to support direct connection to both Ethernet and Fibre Channel networks. This allows a “best of both worlds” approach, using ubiquitous Ethernet networks for regular traffic, and full connection to Fibre Channel networks for lossless applications and the legacy architecture of established Storage Area Networks.

Supported Switch Roles

The G8264CS can be used in the following Fibre Channel applications:

- Node Port Virtualized (NPV) gateway, linking multiple FCoE nodes to an upstream full fabric switch.
- FC-BB-5 compliant full fabric FC/FCoE switch.

These functions are independent of each other, and can coexist or be used in combination on the switch.

The G8264CS acts as a bridge between FCoE traffic and the Fibre Channel network. The switch performs Ethernet encapsulation for traffic heading to Ethernet ports, and performs decapsulation for traffic to Fibre Channel ports.

FCoE features are covered in [“FCoE and CEE” on page 253](#). These features can be used independently or in conjunction with NPV gateway and full fabric switch features.

NPV Gateway

As a Node Port Virtualized (NPV) gateway, the G8264CS can act as a Fibre Channel collector, connecting numerous Fibre Channel end-point devices (known as nodes) for uplink to a Fibre Channel full fabric switch, performing stateless FC/FCoE encapsulation and decapsulation.

This helps resolve a typical problem in Fibre Channel networks where port density is low on Director Class SAN switches, or considered too valuable to relegate to individual nodes. As an NPV gateway, the G8264CS acts as a proxy to the upstream full fabric switch on behalf of the connected nodes.

The G8264CS supports standard Node Port Identifier Virtualization (NPIV) behavior.

The NPV gateway allows concurrent logins from multiple node ports (and multiple server connections) to be forwarded upstream to the full-fabric switch.

The upstream switch provides full fabric services such as zoning enforcement, and makes all switching decisions.

The gateway switch appears as a Fibre Channel end node to the full fabric switch, and acts as proxy for the full fabric switch to its connected node devices.

When multiple uplink ports are available between the NPV gateway and the upstream switch, nodes are not ensured to be assigned the same uplink whenever they request a session.

Only FCoE end nodes are allowed to be downstream connections. All Fibre Channel devices will be connected to the full fabric FC switch.

Full-Fabric FC/FCoE Switch

As a full fabric FC/FCoE switch, the G8264CS authenticates connecting neighbors, provides Fibre Channel IDs, enforces port security among zones, and informs neighboring devices of network changes.

When acting as a full-fabric switch, the G8264CS can be connected to NPV gateways or directly to Fibre Channel nodes. In full-fabric mode, the G8264CS can be connected directly to another full-fabric G8264CS through Fibre Channel ISL. See [“E_Ports” on page 319](#) for more information.

Limitations

In Lenovo N/OS 8.2, the G8264CS does not support the following Fibre Channel port types:

- FL_ports connecting storage fabric loop devices.
- In NPV Gateway mode, Fibre Channel ports connected to NP-F devices.

Implementing Fibre Channel

This section describes the basic elements of Fibre Channel configuration. For examples combining these elements, see [“Fibre Channel Configuration” on page 296](#)

Note: If you need to change the Fibre Channel configuration mode from BBI to ISCLI, first save the configuration using the **save** button on the BBI. Do not use two configuration modes at the same time.

Port Modes

The G8264CS has the following types of network port:

- **High-Capacity Ethernet Ports**

Ports 1-16

These 40Gb QSFP+ Ethernet ports can be configured as either four 40Gb Ethernet ports (1, 5, 9, and 13), or as 16 10Gb Ethernet ports (1-4, 5-8, 9-12, and 13-16).

- **Ethernet Ports**

Ports 17-52

These standard 10Gb SFP+ Ethernet ports provide external connectors.

- **Omni Ports (External)**

Ports 53-64

These 10Gb SFP+ hybrid ports can be configured to operate either in Ethernet mode (the default) or in Fibre Channel mode for direct connection to Fibre Channel devices.

All Ethernet ports (including the Omni Ports by default) can carry any Ethernet data traffic, including Fibre Channel over Ethernet (FCoE) traffic.

When configured to operate in Fibre Channel mode, Omni Ports can be used as Fibre Channel downlinks (connected to Fibre Channel servers or storage devices) or as uplinks (connected to the data center SAN network).

The Omni Port mode (Ethernet or Fibre Channel) can be changed only for pairs of ports. The following port pairs share the same mode: 53-54, 55-56, 57-58, 59-60, 61-62, 63-64.

Paired ports need not be connected to the same device and can even be used in different VLANs. The only required mutual attribute is the network type (Ethernet or Fibre Channel).

Fibre Channel configuration requires that at least one pair of Omni Ports be set to Fibre Channel mode.

The mode for Omni Port pairs or ranges can be configured using the following privileged configuration command:

```
RS 8264CS(config)# [no] system port <low port>-<high port> type fc
```

Fibre Channel VLANs

On the G8264CS, each Fibre Channel network connected to the switch must be assigned its own VLAN. For each VLAN used with Fibre Channel, following properties must be defined:

- VLAN number
- Switch role (NPV mode or full fabric mode)
- Port membership
- Fibre Channel ports roles (as uplink ports or node connections)

The following commands are used to define a typical VLAN:

- Set or delete a VLAN

```
RS 8264CS(config)# [no] vlan <VLAN number>
```

FCoE networks typically use VLAN 1002. If using a different VLAN for FCoE, be sure that any connected servers and FCoE bridge will support your selection.

This command initiates VLAN configuration mode. All VLAN-related Fibre Channel configuration is performed in this mode.

- Enable or disable the VLAN

```
RS 8264CS(config-vlan)# [no] enable
```

- Exit VLAN configuration mode

```
RS 8264CS(config-vlan)# exit
```

See [“Fibre Channel Configuration” on page 296](#) for command examples. For more VLAN information, see [Chapter 9, “VLANs.”](#)

Port Membership

As with typical VLAN configuration, each VLAN used with a Fibre Channel network must include a description of its port members. VLANs used in Fibre Channel networks follow typical VLAN configuration rules (see [“VLANs” on page 123](#)), with the following additions:

- An FC port may belong to only one Fibre Channel VLAN.
- VLAN tagging is automatically enabled for VLANs where NPV mode or full fabric mode is enabled.
- At least one Fibre Channel port must be included in each Fibre Channel VLAN.

From within VLAN configuration mode, the following command is used to add or remove port members:

```
RS 8264CS(config)# interface port <port number, alias, list, or range>  
RS 8264CS(config-if)# switchport trunk allowed vlan [add|remove] <VLAN ID>
```

For example:

```
RS 8264CS(config)# interface port 1,3-4
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan 1,1002
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface fc 62
RS 8264CS(config-if)# switchport trunk allowed vlan 1,1002
RS 8264CS(config-if)# exit
```

Notes:

- The FCoE ports and FC Omni Ports must also be members of VLAN 1 and the Fibre Channel VLAN.
- If using the BBI to add ports or remove ports to or from a Fibre Channel VLAN, first apply the change and then proceed with further configuration.

Switching Mode

The switch's role in the Fibre Channel network can be defined on a per-VLAN basis. The administrator can specify one of the following modes:

- NPV mode to uplink one or more nodes to a full fabric switch or Fibre Channel devices
- Full fabric mode

The G8264CS supports up to 12 Fibre Channel VLANs at any given time. Only one mode can be active on any specific VLAN at a given time, and only one VLAN can operate in full fabric mode.

From within VLAN configuration mode, the following commands are used to specify the Fibre Channel mode:

- To enable or disable NPV mode:

```
RS 8264CS(config-vlan)# [no] npv enable
```

- To enable or disable full fabric mode:

```
RS 8264CS(config-vlan)# [no] fcf enable
```

Note: When either NPV or full fabric mode are enabled, VLAN tagging is automatically enabled on the VLAN.

NPV Gateway

The following section discusses NPV gateways.

NPV Port Traffic Mapping

Within each VLAN used with Fibre Channel, the physical ports may be used in the following roles:

- NPV External Interfaces

The NPV external interface map specifies which Fibre Channel port or ports (Omni Ports set to Fibre Channel mode) are used for this purpose within each Fibre Channel VLAN. At least one Fibre Channel port is required, though two are typically used in order to provide redundancy. The following VLAN configuration command is used to define or remove the uplink:

```
RS 8264CS(config-vlan)# [no] npv traffic-map external-interface <ports>
```

- Fibre Channel over Ethernet node

Traffic from Ethernet ports which are properly configured to use CEE and FCoE (see [“FCoE and CEE” on page 253](#)) is permitted with no additional configuration.

- Ethernet

Traffic on regular (non-FCoE) Ethernet ports will be blocked on Fibre Channel VLANs.

NPV Manual Disruptive Load-Balancing

Every server connected to the NPV gateway logs into an upstream FC switch through a NP uplink. If multiple NP uplinks are available in an NPV VLAN, the logins are evenly distributed over the available uplinks.

The number of logins per uplink can go out of balance if a failed NP uplink is restored or a new uplink is brought online. The NPV gateway does not automatically move Enodes from the existing to new uplinks in such situations. To force the logins to be evenly distributed among all available uplinks in a NPV vlan, the manual load-balancing CLI is available under the vlan config:

```
RS 8264CS(config-vlan)# npv disruptive-load-balance
```

The load-balancing is disruptive in nature as few devices are forced to logout and initiate a re-login. The switch attempts to limit disruption by moving the fewest nodes necessary.

Limitations

Only Emulex CNAs participate in load-balancing. FCoE targets(Ex: V7000) are not load-balanced.

Other CNAs (Ex. Qlogic) store FCF information and try to login to the same FCF (uplink), so they are not balanced.

The CLI addresses only the current imbalance. The CLI must be run again if any event causes uneven distribution in the future.

Full Fabric Zoning

The G8264CS supports Fibre Channel zones and zonesets for VLANs operating in full fabric mode. In NPV gateway mode, zoning is controlled by the upstream full fabric switch and is not configurable in the NPV gateway VLAN.

Zoning allows logical grouping of ports and storage devices within a storage area network. Zoning defines access control between groups of servers and storage devices.

A SAN typically is divided into zones and zonesets, as described in the following sections.

Zones

A *zone* is a logical grouping of end nodes that are permitted to interact with each other. Zones can be grouped into a zonesets, which can be activated or deactivated as a single entity. A zone provides security by restricting access to only those devices that reside within the zone. Zoning also confines change notification floods within each zone.

Each zone contains one or more servers and one or more storage devices. Ports and devices in a zone are called zone members. A zone contains one or more zone members. A device can belong to one or more zones. End nodes that are members of a zone can communicate with each other, but they are isolated from nodes in other zones of which they are not a member.

If no zone is configured for the device, it resides in the default zone. You can configure the default zone to permit or deny its member devices to communicate with each other.

You can specify zone members based on any of the following criteria:

- **pWWN:** The port World Wide Number is a unique ID representing a particular end node. The pWWN is a 64-bit hexadecimal value (for example, 20:34:00:80:e5:23:f4:55)
- **FC ID:** The Fibre Channel identifier (FC ID) specifies the unique fabric domain ID of a device that connects to a node port on the switch. The FC ID is assigned by the full-fabric switch during the connection sequence and can change if the device logs out of the Fibre Channel fabric and returns. The FC ID is a 24-bit hexadecimal value (for example, 0xab00c1), but can also be specified in hexadecimal dotted notation (for example, ab.00.c1) generally representing *<domain or device>.<area>.<link>*
- **FC alias:** The Fibre Channel alias specifies the device that connects to a node port on the switch. The FC alias is a 1-64 character text value (for example, StorageOne).

Notes:

- When you create an FC alias using SNMP, a default pWWN of value 10:00:00:00:00:00:00:00 is automatically assigned to the FC alias. You must change this default pWWN value. Not doing so will result in a conflict of pWWN IDs the next time you try to create an FC alias.
- The G8264CS uses hard zoning, which is enforced in the switch hardware, based on the pWWNs of the Fibre Channel initiators and targets.

The G8264CS supports up to 64 zones per zoneset, each with up to 20 member devices. However, when an FC alias is used, only 10 devices can be members of a zone.

Zonesets

Zonesets provide a mechanism for conveniently grouping zones. Each zoneset can contain one or more zones. A zone can belong to one or more zonesets.

Only one zoneset can be activated at a given time. If you deactivate the active zoneset, no zonesets are active until you activate another zoneset. If you activate one zoneset while another zoneset is active, the currently active zoneset is deactivated.

When you activate a zoneset, the new zoneset access policies are applied.

Up to four zonesets can be configured on the switch at any given time, though only one can be active.

Without zoning configuration, none of the Storage targets is visible to hosts. The default-zone configuration can be made “permit all” using the command:

```
RS 8264CS(config)# zone default-zone permit vlan <VLAN ID>
```

By default the default-zone status is “deny all”.

For security reasons, it is highly recommended that you activate a well-defined zoning configuration.

Defining Zoning

Define the following general properties for Fibre Channel zones and zonesets:

1. If desired, create (or remove) aliases for Fibre Channel devices:

```
RS 8264CS(config)# [no] fcalias <device alias name> wwn <port World Wide Name>
```

Repeat for each alias as necessary.

2. For each desired zone:

- a. Name (or remove) the zone.

```
RS 8264CS(config)# [no] zone name <zone name>
```

- b. Add (or remove) one or more members to the zone using either pWWNs, FC IDs, or FC Aliases

```
RS 8264CS(config-zone)# [no] member pwn <port World Wide Name>  
RS 8264CS(config-zone)# [no] member fcid <Fibre Channel ID>  
RS 8264CS(config-zone)# [no] member fcalias <device alias name>
```

Repeat as necessary for each member device.

- c. Exit from zone configuration:

```
RS 8264CS(config-zone)# exit
```

3. For each desired zoneset:

a. Name (or remove) the zoneset.

```
RS 8264CS(config)# [no] zoneset name <zoneset name>
```

b. Add (or remove) one or more member zones to the zoneset:

```
RS 8264CS(config-zoneset)# [no] member <zone name>
```

Repeat as necessary for each member zone.

c. Exit from zoneset configuration:

```
RS 8264CS(config-zone)# exit
```

Activating a Zoneset

Fibre Channel is intended to operate with minimal disruption. To prevent the various synchronization events that would result if each stage of a live zoning configuration was applied, the cumulative configuration changes for zones and zoneset are held in reserve until explicitly activated by the administrator.

When activated, the new zoneset will be synchronized throughout the Fibre Channel fabric for each modified zone. Fibre Channel traffic will be temporarily disrupted in modified zones as changes to the fabric are recognized by the connected devices. Until activation, the previously established zoneset will remain in effect.

The basic zoneset commands are as follows:

- Activate or deactivate a zoneset:

```
RS 8264CS(config)# [no] zoneset activate name <zoneset name>
```

- View the settings for the active zoneset:

```
RS 8264CS# show zoneset active
```

- View the settings for the pending configuration changes:

```
RS 8264CS# show zoneset
```

E_Ports

E_ports (expansion ports) connect two full-fabric switches to form an inter-switch link (ISL). Up to four Fibre Channel ISLs can be established between two full-fabric switches.

Only Fibre Channel port types can be configured as E-ports. These ports must be members of a Fibre Channel VLAN. Use the following commands to configure E_ports:

```
RS 8264CS(config)# system port <port range> type fc
RS 8264CS(confifg)# interface fc <port range>
RS 8264CS(config-if)# type e
```

To verify the port configuration and operational state, use the following command:

```
RS 8264CS(config)# show interface fc information
```

If different zones were configured on the switches being connected using E_ports, the zones merge to establish a consistent zoning policy across the fabric. The zones on the two switches must belong to any one zoneset.

Note: Zones are added in the merged zoneset only if the zoneset on the individual switch was active.

Table 27 lists the zone merge rules.

Table 27. *Zone Merge Rules*

Adjacent Zoning Configuration	Local Zoning Configuration	Result in Local Switch
Zone Set State is Deactivated.	Zone Set State is Activated or Deactivated.	No change
Zone Set State is Activated.	Zone Set State is Deactivated.	Zone Set gets the Adjacent Zone Set State (the Zone Set is activated). Zone Set gets the adjacent Zone Set.
Adjacent Zone Set is equal to the Local Zone Set		No change
Adjacent and Local Zone Sets contain a Zone with the same name but different members.		ISL Isolated.
Adjacent Zone Set contains Zones that are not included in the Local Zone Set, and/or Local Zone Set contains Zones that are not included in the Adjacent Zone Set.		Zone Set becomes Activated. Zone Set is the merge of the local Zones plus the Adjacent Zones.

Limitations

- Lenovo Networking OS supports ISL distance up to 3 kms.
- E_ports can be configured only on Lenovo RackSwitch G8264CS and Lenovo Flex System Fabric CN4093 10Gb Converged Scalable Switch. E_ports cannot interoperate with the switches from other vendors.
- A maximum of eight switches are supported in a Fibre Channel fabric.
- A maximum of four E_ports can be configured on a switch.

Optimized FCoE Traffic Flow

To optimize FCoE traffic flow between FCoE enodes, the optimized-forwarding feature installs appropriate ACL entries for logged-in nodes. Most of the time, FC/FCoE traffic in full-fabric mode needs to go through an FC module for Zone checking. You can achieve low latency if the Zone check is done on Ethernet switch module for FCoE-FCoE traffic. The optimized-forwarding feature is enabled by default in full-fabric mode but is not applicable to NPV mode.

Note: FCoE-FC and FC-FC traffic is not optimized.

If needed, you can disable optimized-forwarding feature. Before you do, you must disable FIP snooping. Use the following commands:

```
RS 8264CS(config)# no fcoe fips enable
RS 8264CS(config)# no fcoe optimized-forwarding enable
```

To re-enable optimized-forwarding feature, use the following command sequence:

```
RS 8264CS(config)# no fcoe fips enable
RS 8264CS(config)# fcoe optimized-forwarding enable
RS 8264CS(config)# fcoe fips enable
```

To view optimized traffic flow information, use the following commands:

```
RS 8264CS(config)# show fcoe optimized-forwarding status
                                     (Show current state of feature)
RS 8264CS(config)# show fcoe optimized-acls vlan <vlan ID>
                                     (Show list of optimized ACLs)
```

Storage Management Initiative Specification (SMI-S)

Lenovo Networking OS provides a programming interface using the SMI-S to ease interoperability in a multivendor SAN environment. In this release, only limited support is provided. The G8264CS switch must be operating in full fabric mode.

An embedded SMI-S agent runs on the G8264CS and includes standard profiles as specified in the SMI-S. These profiles include:

- Fabric Profile
- Indication Profile
- Server Profile
- Switch Profile

Configuration capabilities of switch, fabric, or ports is not supported. Zoning control can be implemented and includes the following functions:

- Session control (start, commit, and rollback)
- Zoning updates
- Create and destroy zone set, zone, and zone alias
- Add/Remove zone to zone set, zone alias, or port WWN to zone and port WWN to zone alias
- Activate and deactivate zoneset

The IBM Director (includes Tivoli Storage Productivity Center (TPC)) is used to configure and administer the fibre channel fabric. Connection with the SMI-S agent can be established via IPv4 or IPv6 management interface using HTTP/HTTPS. Use the following link:

```
http://<Management IP address>:5988  
(OR)  
https://<Management IP address>:5989
```

The namespace for the SMI-S agent is root/interop.

You will need to authenticate using the login and password configured for the switch.

Restrictions

The current implementation of SMI-S does not support the following:

- NPV mode
- Switch port zoning
- Zone configuration on the switch that uses FC IDs instead of port WWNs.

Note: The CLI commands may be available, but the zone configuration will not be applied.

Fibre Channel Configuration

Configuration Guidelines

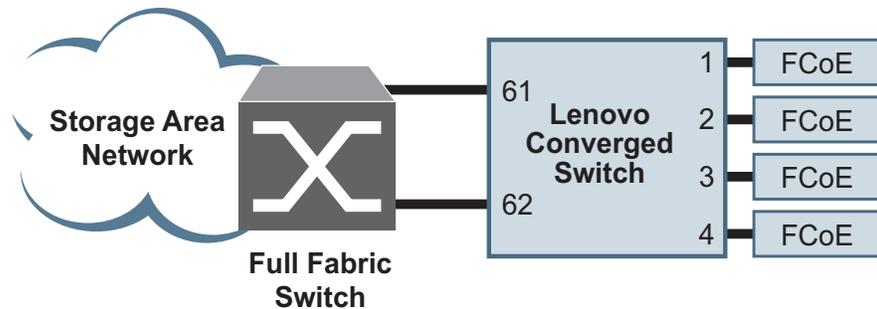

In Lenovo N/OS 8.2, consider the following when configuring Fibre Channel on the G8264CS:

- Up to 12 Fibre Channel networks (on separate VLANs) are supported.
- Only one Fibre Channel VLAN can operate in full fabric mode at any given time. All others can operate as NPV gateways.
- Only Omni Ports (53-64) can be placed in Fibre Channel mode. All other ports operate in Ethernet mode, which may participate in Fibre Channel networks as FCoE nodes.
- At least one Omni Port is required to operate in Fibre Channel mode in each Fibre Channel VLAN.
- Zones and zonesets apply only to a VLAN in full fabric mode. Up to 4 zonesets may be configured, but only 1 can be active at any given time. The G8264CS supports up to 64 zones per zoneset, each with up to 20 member devices. However, when an FC alias is used, only 10 devices can be members of a zone.

Example 1: NPV Gateway

In this example, the G8264CS operates as an NPV gateway:

Figure 31. Using the G8264CS as an NPV Gateway

The switch connects to FCoE node ports to an external Fibre Channel full fabric switch. Because multiple nodes will share the G8264CS uplinks, the network must be configured as an NPV gateway.

Note: Up to 12 Fibre Channel VLANs can be configured on the switch at any given time, any or all of which can be configured as NPV gateways.

1. Specify which Omni Ports are directly connected to Fibre Channel devices:

```
RS 8264CS(config)# system port 61-62 type fc
```

Note: On the G8264CS, FC devices can be connected only to Omni Ports. Omni Ports connected to FCoE devices are considered part of the Ethernet network and should be left to operate in Ethernet mode.

2. Enable tagging for internal ports participating in FCoE:

```
RS 8264CS(config)# interface port 1-4
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

3. Specify all member ports for the VLAN:

```
RS 8264CS(config-vlan)# interface port 1-4
RS 8264CS(config-vlan)# switchport trunk allowed vlan add 1002
RS 8264CS(config-vlan)# interface fc 61-62
RS 8264CS(config-vlan)# switchport trunk allowed vlan add 1002
```

4. Specify a VLAN for this Fibre Channel network:

```
RS 8264CS(config)# vlan 1002
```

5. Enable NPV mode on the VLAN:

```
RS 8264CS(config-vlan)# npv enable
RS 8264CS(config-vlan)# exit
```

6. Specify which external ports are connected to the upstream Fibre Channel full fabric switch:

```
RS 8264CS(config-vlan)# npv traffic-map external-interface 61-62
RS 8264CS(config-vlan)# exit
```

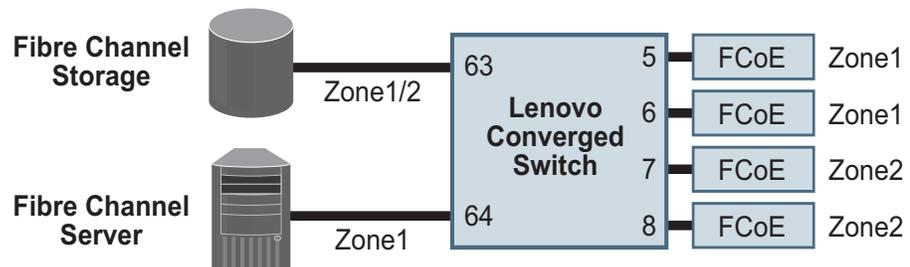

Note: Although this example depicts two Fibre Channel ports connected to the upstream device, this is done for the sake of network redundancy. Only one Fibre Channel port is actually required.

7. Remove unused ports—ports that are not part of the uplink to the Fibre Channel fabric—from the NPV VLAN.

Example 2: Full Fabric FC/FCoE Switch

Consider the following Fibre Channel network:

Figure 32. Using the G8264CS as a Full Fabric FC/FCoE Switch

In this example network, the G8264CS acts as the full fabric switch for the Fibre Channel network in two zones.

Note: Although up to 12 Fibre Channel VLANs can be configured on the switch at any given time, only one can operate in full fabric mode. The rest may be configured as NPV gateways. For instance, the full fabric configuration in this example can be used simultaneously with up to 11 NPV gateways configured as shown in the NPV example on [page 297](#).

1. Specify which Omni Ports will be used for Fibre Channel devices:

```
RS 8264CS(config)# system port 63-64 type fc
```

Note: On the G8264CS, Fibre Channel devices can be connected only to Omni Ports. Omni Ports connected to FCoE devices are considered part of the Ethernet network and should be left to operate in Ethernet mode.

2. Enable tagging for internal ports participating in FCoE:

```
RS 8264CS(config)# interface port 5-8
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit
```

3. Specify a VLAN for the this Fibre Channel network:

```
RS 8264CS(config)# vlan 200
RS 8264CS(config-vlan)# enable
```

4. Specify all member ports for the VLAN:

```
RS 8264CS(config-vlan)# member 5-8, 63-64
```

Note: At least one Fibre Channel port must be included.

5. Enable full fabric mode on the VLAN:

```
RS 8264CS(config-vlan)# fcf enable
RS 8264CS(config-vlan)# exit
```

6. Define Fibre Channel zones:

```
RS 8264CS(config)# zone name Zone1
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:23:b1:55
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:27:f4:56
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:28:31:13
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:28:31:14
RS 8264CS(config-zone)# exit
RS 8264CS(config)# zone name Zone2
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:28:43:57
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:18:b3:58
RS 8264CS(config-zone)# member pwn 20:34:00:80:e5:28:31:13
RS 8264CS(config-zone)# exit
RS 8264CS(config)# zoneset name City1
RS 8264CS(config-zoneset)# member Zone1
RS 8264CS(config-zoneset)# member Zone2
RS 8264CS(config-zoneset)# exit
RS 8264CS(config)# zoneset activate name City1
```

Fibre Channel Standard Protocols Supported

Following table lists the standard FC protocols supported on the RackSwitch G8264CS.

Table 28. *FC Protocols Supported*

Protocol
Fibre Channel FCoE · T11 FCoE Initialization Protocol (FIP) (FC-BB-5)
Fibre Channel forwarding (FCF)
Port Types Fibre Channel: F, NP, NP-F, VF E (N/OS 7.8 onwards)
Sixteen Buffer credits supported:
Fabric Device Management Interface (FDMI)
NPIV
NPV Gateway
Fabric Shortest Path First (FSPF)
Port security
Fibre Channel ping, debugging
Fibre Channel Standards: <ul style="list-style-type: none"> • FC-PH, Revision 4.3 (ANSI/INCITS 230-1994) • FC-PH, Amendment 1 (ANSI/INCITS 230-1994/AM1 1996) • FC-PH, Amendment 2 (ANSI/INCITS 230-1994/AM2-1999) • FC-PH-2, Revision 7.4 (ANSI/INCITS 297-1997) • FC-PH-3, Revision 9.4 (ANSI/INCITS 303-1998) • FC-PI, Revision 13 (ANSI/INCITS 352-2002) • FC-PI-2, Revision 10 (ANSI/INCITS 404-2006) • FC-PI-4, Revision 7.0 • FC-FS, Revision 1.9 (ANSI/INCITS 373-2003) • FC-FS-2, Revision 0.91 • FC_FS_3 Revision 1.11 • FC-LS, Revision 1.2 • FC-SW-2, Revision 5.3 (ANSI/INCITS 355-2001) • FC-SW-3, Revision 6.6 (ANSI/INCITS 384-2004) • FC-SW-5, Revision 8.5 (ANSI/INCITS 461-2010) • FC-GS-3, Revision 7.01 (ANSI/INCITS 348-2001) • FC-GS-4, Revision 7.91 (ANSI/INCITS 387-2004) • FC-GS-6 Revision 9.4 (ANSI/INCITS 463-2010) • FC-BB-5, Revision 2.0 for FCoE • FCP, Revision 12 (ANSI/INCITS 269-1996) • FCP-2, Revision 8 (ANSI/INCITS 350-2003) • FCP-3, Revision 4 (ANSI/INCITS 416-2006) • FC-MI, Revision 1.92 (INCITS TR-30-2002, except for FL-ports and Class 2) • FC-MI-2, Revision 2.6 (INCITS TR-39-2005) • FC-SP, Revision 1.6 • FC-DA, Revision 3.1 (INCITS TR-36-2004)

Chapter 19. Edge Virtual Bridging

The 802.1Qbg/Edge Virtual Bridging (EVB) is an emerging IEEE standard for allowing networks to become virtual machine (VM)-aware. EVB bridges the gap between physical and virtual network resources. The IEEE 802.1Qbg simplifies network management by providing a standards-based protocol that defines how virtual Ethernet bridges exchange configuration information. In EVB environments, physical end stations, containing multiple virtual end stations, use a bridge to form a LAN. The virtual NIC (vNIC) configuration information of a virtual machine is available to these EVB devices. This information is generally not available to an 802.1Q bridge.

Lenovo Networking OS EVB features are compliant with the IEEE 802.1Qbg Authors Group Draft 0.2. For a list of documents on this feature, see: <http://www.ieee802.org/1/pages/802.1bg.html>.

The RackSwitch G8264CS performs the role of a 802.1Qbg bridge in an EVB environment.

Lenovo N/OS implementation of EVB supports the following protocols:

- Virtual Ethernet Bridging (VEB) and Virtual Ethernet Port Aggregator (VEPA): VEB and VEPA are mechanisms for switching between VMs on the same hypervisor. VEB enables switching with the server, either in the software (vSwitch), or in the hardware (using single root I/O virtualization capable NICs). VEPA requires the edge switch to support “Reflective Relay” — an operation where the switch forwards a frame back to the port on which it arrived if the destination MAC address is on the same port.
- Edge Control Protocol (ECP): ECP is a transport protocol that operates between two peers over an IEEE 802 LAN. ECP provides reliable, in-order delivery of ULP (Upper Layer Protocol) PDUs (Protocol Data Units).
- Virtual Station Interface (VSI) Discovery and Configuration Protocol (VDP): VDP allows hypervisors to advertise VSIs to the physical network. This protocol also allows centralized configuration of network policies that will persist with the VM, independent of its location.
- EVB Type-Length-Value (TLV): EVB TLV is a Link Layer Discovery protocol (LLDP)-based TLV used to discover and configure VEPA, ECP, and VDP.

EVB Operations Overview

The N/OS includes a pre-standards VSI Type Database (VSIDB) implemented through the System Networking Switch Center (SNSC), the Flex System Manager (FSM), or the IBM System Networking Distributed Switch 5000V. The VSIDB is the central repository for defining sets of network policies that apply to VM network ports. You can configure only one VSIDB.

Note: This document does not include the VSIDB configuration details. Please see the SNSC, FSM, or IBM System Networking Distributed Switch 5000V guide for details on how to configure VSIDB.

The VSIDB operates in the following sequence:

1. Define VSI types in the VSIDB. The VSIDB exports the database when the G8264CS sends a request.
2. Create a VM. Specify VSI type for each VM interface. See the SNSC, FSM, or IBM System Networking Distributed Switch 5000V guide for details on how to specify the VSI type.

The hypervisor sends a VSI ASSOCIATE, which contains the VSI type ID, to the switch port after the VM is started. The switch updates its configuration based on the requested VSI type. The switch configures the per-VM bandwidth using the VMpolicy.

The N/OS supports the following policies for VMs:

- ACLs
- Bandwidth metering

VSIDB Synchronization

The switch periodically checks for VSIDB changes based on the configured interval. You can configure this interval using the following command:

```
RS 8264CS(config)# virt evb vsidb <number>
RS 8264CS(conf-vsldb)# update-interval <time in seconds>
```

To disable periodic updates, configure the interval value as 0.

If the switch finds that the VSIDB has changed, it updates the local VSIDB cache. When the cache is successfully updated, it sends a syslog message.

After updating the local VSIDB cache, the switch disassociates any VM whose type ID or VLAN no longer exists in the updated cache.

The switch updates the local VSIDB cache when any of the following takes place:

- When, at the configured refresh interval, the switch finds that the VSIDB configuration has changed since the last poll.
- When a VM sends an ASSOCIATE message, but the VSI type does not exist in the local VSIDB cache.
- When a VM sends an ASSOCIATE message, and the VSI type exists but the VSI type's VLAN ID does not exist in the local VSIDB cache.

- When you update the VSIDB using the following command:
RS 8264CS# virt evb update vsidb <number>
- When the management port link status changes from down to up

VLAN Behavior

When a VM gets associated, the corresponding VLAN is dynamically created on the switch port if the VLAN does not already exist.

VLANs that are dynamically created will be automatically removed from the switch port when there are no VMs using that VLAN on the port.

Dynamic VLAN information will not be displayed in the running configuration. However, the VLAN, port, and STP commands display the dynamic VLAN information with a “*”.

If you configure any Layer 2/Layer 3 features on dynamically created VLANs, the VLAN information is displayed in the running configuration.

Deleting a VLAN

If you delete a VLAN that has a VM associated with it, you will see a warning message similar to the following:

```
Warning: Vlan 10 is used by VM and can't be removed.
```

The VMs will not get disassociated.

If a VM is associated with a port, and you remove this port from a VLAN, you will see a warning message similar to the following:

```
Warning: Port 23 in Vlan 10 is used by VM and can't be removed.
```

The VMs will not get disassociated.

Manual Reflective Relay

Reflective Relay (RR) is an operation where the switch forwards a frame back to the port on which it arrived if the destination MAC address is on the same port. When an EVB profile is configured on a port, RR is automatically enabled on the port after capability exchange with the peer, using the IEEE802.1QBG protocol. This is the usual mode of operation.

When the switch interoperates with devices that do not support IEEE 802.1QBG protocols, RR can be manually configured using the following command:

```
RS 8264CS(config-if)# reflective-relay force enable
```

Manual RR and EVB profile cannot be configured on a port at the same time.

EVB Configuration

This section includes the steps to configure EVB based on the following values:

- Profile number: 1
- Port number: 1
- Retry interval: 8000 milliseconds
- VSI Database:
 - Manager IP: 172.31.37.187
 - Port: 80

Note: VSI Database can be accessed via HTTP or HTTPS. The manager IP can be configured with an IPv4 or IPv6 address.

1. Create an EVB profile.

```
RS 8264CS(config)# virt evb profile 1 (Enter number from 1-16)
```

2. Enable Reflective Relay.

```
RS 8264CS(conf-evbprof)# reflective-relay
```

3. Enable VSI discovery.

```
RS 8264CS(conf-evbprof)# vsi-discovery  
RS 8264CS(conf-evbprof)# exit
```

4. Add EVB profile to port.

```
RS 8264CS(config)# interface port 1  
RS 8264CS(config-if)# evb profile 1 (Enter EVB profile ID)  
RS 8264CS(config-if)# exit
```

Note: This port must be a server port (RS 8264CS(config)# system server-ports port <port number>)

5. Configure ECP retransmission interval.

```
RS 8264CS(config)# ecp retransmit-interval 8000  
(Enter retransmission interval in milliseconds (100-9000))
```

6. Set VSI database information.

```
RS 8264CS(config)# virt evb vsidb 1
RS 8264CS(config-vsidb)# protocol {http|https} (Select VSI database protocol; default is
HTTP)
RS 8264CS(config-vsidb)# host 172.31.37.187 [data-port|mgt-port]
(Set VSI database Manager IP)
RS 8264CS(config-vsidb)# port 80 (Set VSI database Manager port)
RS 8264CS(config-vsidb)# filepath "vsidb" (Set VSI database document path)
RS 8264CS(config-vsidb)# filename "all.xml" (Set VSI database file name)
RS 8264CS(config-vsidb)# update-interval 30 (Set update interval in seconds)
RS 8264CS(config-vsidb)# exit
```

Note: When you connect to a SNSC VSIDB, the port/docpath configuration is as follows:

HTTP:

- Port: 40080
- Docpath: snc/rest/vsitypes

HTTPS:

- Port: 40443
- Docpath: snc/rest/vsitypes

When you connect to a 5000v VSIDB, the port/docpath configuration is as follows:

- Port: 80
- Docpath: vsitypes

7. Enable LLDP.

```
RS 8264CS(config)# lldp enable (Turn on LLDP)
```

Limitations

- If both ACL and egress bandwidth metering are enabled, traffic will first be matched with the ACL and will not be limited by bandwidth metering.
- ACLs based on a source MAC or VLAN must match the source MAC and VLAN of the VM. If not, the policy will be ignored and you will see the following warning message:

```
"vm: VSI Type ID 100 Associated mac 00:50:56:b6:c0:ff on port 6,  
ignore 1 mismatched ACL"
```

Unsupported features

The following features are not supported with EVB:

- LAG/VLAG
- vNIC

Chapter 20. Static Multicast ARP

The Microsoft Windows operating system includes the Network Load Balancing (NLB) technology that helps to balance incoming IP traffic among multi-node clusters. In multicast mode, NLB uses a shared multicast MAC address with a unicast IP address. Since the address resolution protocol (ARP) can map an IP address to only one MAC address, port, and VLAN, the packet reaches only one of the servers (the one attached to the port on which the ARP was learnt).

To avoid the ARP resolution, you must create a static ARP entry with multicast MAC address. You must also specify the list of ports through which the multicast packet must be sent out from the gateway or Layer 2/Layer 3 node.

With these configurations, a packet with a unicast IPv4 destination address and multicast MAC address can be sent out as per the multicast MAC address configuration. NLB maps the unicast IP address and multicast MAC address as follows:

Cluster multicast MAC address: 03-BF-W-X-Y-Z; where W.X.Y.Z is the cluster unicast IP address.

You must configure the static multicast ARP entry only at the Layer 2/Layer 3 or Router node, and not at the Layer 2-only node.

Lenovo Networking OS supports a maximum of 20 static multicast ARP entries.

Note: If you use the ACL profile, an ACL entry is consumed for each Static Multicast ARP entry that you configure. Hence, you can configure a maximum of 896 ACLs and multicast MAC entries together when using the ACL profile. The ACL entries have a higher priority. In the default profile, the number of static multicast ARP entries that you configure does not affect the total number of ACL entries.

Configuring Static Multicast ARP

To configure multicast MAC ARP, you must perform the following steps:

- Configure the static multicast forwarding database (FDB) entry: Since there is no port list specified for static multicast ARP, and the associated MAC address is multicast, you must specify a static multicast FDB entry for the cluster MAC address to limit the multicast domain. If there is no static multicast FDB entry defined for the cluster MAC address, traffic will not be forwarded. Use the following command:

```
RS 8264CS(config)# mac-address-table multicast <cluster MAC address> <port(s)>
```

- Configure the static multicast ARP entry: Multicast ARP static entries should be configured without specifying the list of ports to be used. Use the following command:

```
RS 8264CS(config)# ip arp <destination unicast IP address> <destination multicast MAC address> vlan <cluster VLAN number>
```

Configuration Example

Consider the following example:

- Cluster unicast IP address: 10.10.10.42
- Cluster multicast MAC address: 03:bf:0A:0A:0A:2A
- Cluster VLAN: 42
- List of individual or port trunks to which traffic should be forwarded: 54 and 56

Following are the steps to configure the static multicast ARP based on the given example:

1. Configure the static multicast FDB entry.

```
RS 8264CS(config)# mac-address-table multicast 03:bf:0A:0A:0A:2A 42 54,56
```

2. Configure the static multicast ARP entry:

```
RS 8264CS(config)# ip arp 10.10.10.42 03:bf:0A:0A:0A:2A vlan 42
```

You can verify the configuration using the following commands:

- Verify static multicast FDB entry:

```
RS 8264CS(config)# show mac-address-table multicast address
03:bf:0A:0A:0A:2A

Multicast Address  VLAN  Port(s)
-----
03:bf:0A:0A:0A:2A  42    54 56
```

- Verify static multicast ARP entry:

```

RS 8264CS(config)# show ip arp

Current ARP configuration:
  rearp 5
Current static ARP:
  ip          mac          port  vlan
  -----
  10.10.10.42  03:bf:0A:0A:0A:2A      42
  -----
Total number of arp entries : 2
  IP address  Flags  MAC address  VLAN  Age Port
  -----
  10.10.10.1  P     fc:cf:62:9d:74:00  42
  10.10.10.42  P     03:bf:0A:0A:0A:2A  42      0

```

Limitations

- You must configure the ARP only in the Layer 2/Layer 3 node or the router node but not in the Layer 2-only node. Lenovo N/OS cannot validate if the node is Layer 2-only.
- The packet is always forwarded to all the ports as specified in the Multicast MAC address configuration. If VLAN membership changes for the ports, you must update this static multicast MAC entry. If not, the ports, whose membership has changed, will report discards.
- ACLs take precedence over static multicast ARP. If an ACL is configured to match and permit ingress of unicast traffic, the traffic will be forwarded based on the ACL rule, and the static multicast ARP will be ignored.

Part 5: IP Routing

This section discusses Layer 3 switching functions. In addition to switching traffic at near line rates, the application switch can perform multi-protocol routing. This section discusses basic routing and advanced routing protocols:

- Basic Routing
- IPv6 Host Management
- Routing Information Protocol (RIP)
- Internet Group Management Protocol (IGMP)
- Border Gateway Protocol (BGP)
- Open Shortest Path First (OSPF)
- Service Location Protocol (SLP)

Chapter 21. Basic IP Routing

This chapter provides configuration background and examples for using the G8264CS to perform IP routing functions. The following topics are addressed in this chapter:

- [“IP Routing Benefits” on page 314](#)
- [“Routing Between IP Subnets” on page 314](#)
- [“Example of Subnet Routing” on page 315](#)
- [“ECMP Static Routes” on page 319](#)
- [“ECMP Static Routes” on page 319](#)
- [“Dynamic Host Configuration Protocol” on page 321](#)

IP Routing Benefits

The switch uses a combination of configurable IP switch interfaces and IP routing options. The switch IP routing capabilities provide the following benefits:

- Connects the server IP subnets to the rest of the backbone network.
- Provides the ability to route IP traffic between multiple Virtual Local Area Networks (VLANs) configured on the switch.

Routing Between IP Subnets

The physical layout of most corporate networks has evolved over time. Classic hub/router topologies have given way to faster switched topologies, particularly now that switches are increasingly intelligent. The G8264CS is intelligent and fast enough to perform routing functions at wire speed.

The combination of faster routing and switching in a single device allows you to build versatile topologies that account for legacy configurations.

For example, consider a corporate campus that has migrated from a router-centric topology to a faster, more powerful, switch-based topology. As is often the case, the legacy of network growth and redesign has left the system with a mix of illogically distributed subnets.

This is a situation that switching alone cannot cure. Instead, the router is flooded with cross-subnet communication. This compromises efficiency in two ways:

- Routers can be slower than switches. The cross-subnet side trip from the switch to the router and back again adds two hops for the data, slowing throughput considerably.
- Traffic to the router increases, increasing congestion.

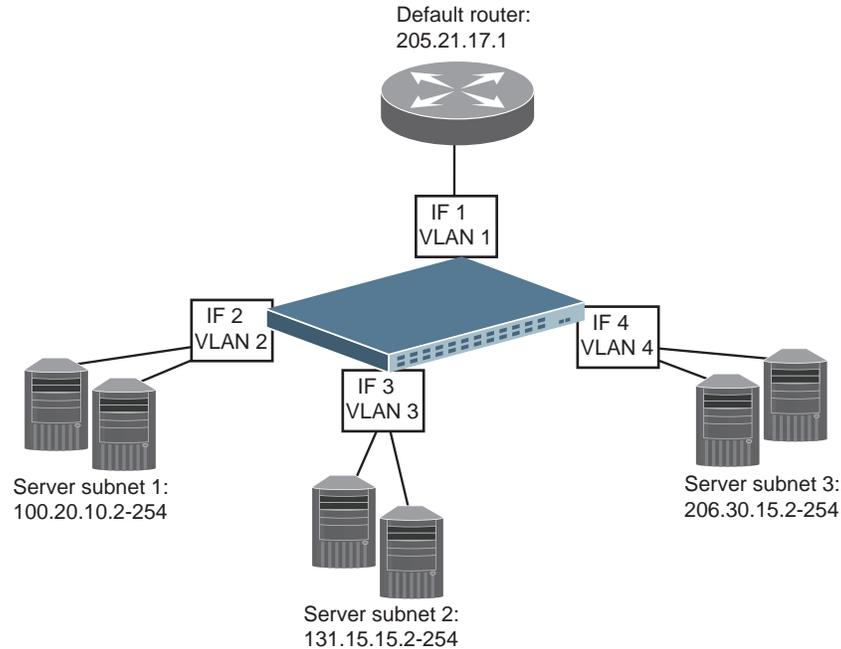

Even if every end-station could be moved to better logical subnets (a daunting task), competition for access to common server pools on different subnets still burdens the routers.

This problem is solved by using switches with built-in IP routing capabilities. Cross-subnet LAN traffic can now be routed within the switches with wire speed switching performance. This eases the load on the router and saves the network administrators from reconfiguring every end-station with new IP addresses.

Example of Subnet Routing

Consider the role of the G8264CS in the following configuration example:

Figure 33. Switch-Based Routing Topology

The switch connects the Gigabit Ethernet and Fast Ethernet trunks from various switched subnets throughout one building. Common servers are placed on another subnet attached to the switch. A primary and backup router are attached to the switch on yet another subnet.

Without Layer 3 IP routing on the switch, cross-subnet communication is relayed to the default gateway (in this case, the router) for the next level of routing intelligence. The router fills in the necessary address information and sends the data back to the switch, which then relays the packet to the proper destination subnet using Layer 2 switching.

With Layer 3 IP routing in place on the switch, routing between different IP subnets can be accomplished entirely within the switch. This leaves the routers free to handle inbound and outbound traffic for this group of subnets.

Using VLANs to Segregate Broadcast Domains

If you want to control the broadcasts on your network, use VLANs to create distinct broadcast domains. Create one VLAN for each server subnet, and one for the router.

Configuration Example

This section describes the steps used to configure the example topology shown in [Figure 33 on page 315](#).

1. Assign an IP address (or document the existing one) for each router and each server.

The following IP addresses are used:

Table 29. *Subnet Routing Example: IP Address Assignments*

Subnet	Devices	IP Addresses
1	Default router	205.21.17.1
2	Web servers	100.20.10.2-254
3	Database servers	131.15.15.2-254
4	Terminal Servers	206.30.15.2-254

2. Assign an IP interface for each subnet attached to the switch.

Since there are four IP subnets connected to the switch, four IP interfaces are needed:

Table 30. *Subnet Routing Example: IP Interface Assignments*

Interface	Devices	IP Interface Address
IF 1	Default router	205.21.17.3
IF 2	Web servers	100.20.10.1
IF 3	Database servers	131.15.15.1
IF 4	Terminal Servers	206.30.15.1

3. Determine which switch ports and IP interfaces belong to which VLANs.

The following table adds port and VLAN information:

Table 31. *Subnet Routing Example: Optional VLAN Ports*

Devices	IP Interface	Switch Ports	VLAN #
Default router	1	22	1
Web servers	2	1 and 2	2
Database servers	3	3 and 4	3
Terminal Servers	4	5 and 6	4

Note: To perform this configuration, you must be connected to the switch Command Line Interface (CLI) as the administrator.

4. Add the switch ports to their respective VLANs.

The VLANs shown in [Table 31](#) are configured as follows:

```
RS 8264CS(config)# vlan 1
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 22 (Add ports to VLAN 1)
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 1
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1,2 (Add ports to VLAN 2)
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 3,4 (Add ports to VLAN 3)
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 3
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 4
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 5,6 (Add ports to VLAN 4)
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 4
RS 8264CS(config-if)# exit
```

Each time you add a port to a VLAN, you may get the following prompt:

```
Port 4 is an untagged port and its PVID is changed from 1 to 3.
```

5. Assign a VLAN to each IP interface.

Now that the ports are separated into VLANs, the VLANs are assigned to the appropriate IP interface for each subnet. From [Table 31 on page 316](#), the settings are made as follows:

```
RS 8264CS(config)# interface ip 1 (Select IP interface 1)
RS 8264CS(config-ip-if)# ip address 205.21.17.3
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 1 (Add VLAN 1)
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface ip 2 (Select IP interface 2)
RS 8264CS(config-ip-if)# ip address 100.20.10.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 2 (Add VLAN 2)
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3 (Select IP interface 3)
RS 8264CS(config-ip-if)# ip address 131.15.15.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 3 (Add VLAN 3)
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 4 (Select IP interface 4)
RS 8264CS(config-ip-if)# ip address 206.30.15.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 4 (Add VLAN 4)
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

6. Configure the default gateway to the routers' addresses.

The default gateway allows the switch to send outbound traffic to the router:

```
RS 8264CS(config)# ip gateway 1 address 205.21.17.1
RS 8264CS(config)# ip gateway 1 enable
```

7. Enable IP routing.

```
RS 8264CS(config)# ip routing
```

8. Verify the configuration.

```
RS 8264CS(config)# show vlan
RS 8264CS(config)# show interface information
RS 8264CS(config)# show interface ip
```

Examine the resulting information. If any settings are incorrect, make the appropriate changes.

ECMP Static Routes

Equal-Cost Multi-Path (ECMP) is a forwarding mechanism that routes packets along multiple paths of equal cost. ECMP provides equally-distributed link load sharing across the paths. The hashing algorithm used is based on the destination IP and source IP (DIPSIP) addresses or only on the source IP address (SIP). ECMP routes allow the switch to choose between several next hops toward a given destination. The switch performs periodic health checks (ping) on each ECMP gateway. If a gateway fails, it is removed from the routing table, and an SNMP trap is sent.

OSPF Integration

When a dynamic route is added through Open Shortest Path First (OSPF), the switch checks the route's gateway against the ECMP static routes. If the gateway matches one of the single or ECMP static route destinations, then the OSPF route is added to the list of ECMP static routes. Traffic is load-balanced across all of the available gateways. When the OSPF dynamic route times out, it is deleted from the list of ECMP static routes.

ECMP Route Hashing

You can configure the parameters used to perform ECMP route hashing, as follows:

- `sip`: Source IP address
- `dipsip`: Source IP address and destination IP address (default)

Note: The `sip` and `dipsip` options enabled under ECMP route hashing or in port trunk hashing (`portchannel thash`) apply to both ECMP and trunk features (the enabled settings are cumulative). If unexpected ECMP route hashing occurs, disable the unwanted source or destination IP address option set in trunk hashing. Likewise, if unexpected trunk hashing occurs, disable any unwanted options set in ECMP route hashing.

The ECMP hash setting applies to all ECMP routes.

Configuring ECMP Static Routes

To configure ECMP static routes, add the same route multiple times, each with the same destination IP address, but with a different gateway IP address. These routes become ECMP routes.

1. Add a static route (IP address, subnet mask, gateway, and interface number).

```
RS 8264CS(config)# ip route 10.10.1.1 255.255.255.255 100.10.1.1 1
```

2. Add another static route with the same IP address and mask, but a different gateway address.

```
RS 8264CS(config)# ip route 10.10.1.1 255.255.255.255 200.20.2.2 1
```

3. Select an ECMP hashing method (optional).

```
RS 8264CS(config)# ip route ecmphash [sip|dipsip]
```

You may add up to 32 gateways for each static route.

Use the following commands to check the status of ECMP static routes:

```
RS 8264CS(config)# show ip route static
Current static routes:
  Destination      Mask                Gateway             If    ECMP
  -----
  10.20.2.2        255.255.255.255   10.4.4.1           *
                   10.5.5.1           *
                   10.6.6.1           *
                   ...
                   10.35.35.1        *
ECMP health-check ping interval: 1
ECMP health-check retries number: 3
ECMP Hash Mechanism: dipsip
Gateway healthcheck: enabled
```

```
RS 8264CS(config)# show ip ecmp
Current ecmp static routes:
  Destination      Mask                Gateway             If    GW Status
  -----
  10.20.2.2        255.255.255.255   10.4.4.1           up
                   10.5.5.1           up
                   10.6.6.1           up
                   ...
                   10.34.34.1        up
                   10.35.35.1        up
```

Dynamic Host Configuration Protocol

Dynamic Host Configuration Protocol (DHCP) is a transport protocol that provides a framework for automatically assigning IP addresses and configuration information to other IP hosts or clients in a large TCP/IP network. Without DHCP, the IP address must be entered manually for each network device. DHCP allows a network administrator to distribute IP addresses from a central point and automatically send a new IP address when a device is connected to a different place in the network.

The switch accepts gateway configuration parameters if they have not been configured manually. The switch ignores DHCP gateway parameters if the gateway is configured.

DHCP is an extension of another network IP management protocol, Bootstrap Protocol (BOOTP), with an additional capability of being able to allocate reusable network addresses and configuration parameters for client operation.

Built on the client/server model, DHCP allows hosts or clients on an IP network to obtain their configurations from a DHCP server, thereby reducing network administration. The most significant configuration the client receives from the server is its required IP address; (other optional parameters include the "generic" file name to be booted, the address of the default gateway, and so forth).

To enable DHCP on a switch interface, use the following command:

```
RS 8264CS(config)# system dhcp
```

DHCP Relay Agent

DHCP is described in RFC 2131, and the DHCP relay agent supported on the G8264CS is described in RFC 1542. DHCP uses UDP as its transport protocol. The client sends messages to the server on port 67 and the server sends messages to the client on port 68.

DHCP defines the methods through which clients can be assigned an IP address for a finite lease period and allowing reassignment of the IP address to another client later. Additionally, DHCP provides the mechanism for a client to gather other IP configuration parameters it needs to operate in the TCP/IP network.

In the DHCP environment, the G8264CS can act as a relay agent. The DHCP relay feature enables the switch to forward a client request for an IP address to two BOOTP servers with IP addresses that have been configured on the switch.

When a switch receives a UDP broadcast on port 67 from a DHCP client requesting an IP address, the switch acts as a proxy for the client, replacing the client source IP (SIP) and destination IP (DIP) addresses. The request is then forwarded as a UDP Unicast MAC layer message to two BOOTP servers whose IP addresses are configured on the switch. The servers respond as a UDP Unicast message back to the switch, with the default gateway and IP address for the client. The destination IP address in the server response represents the interface address on the switch that received the client request. This interface address tells the switch on which VLAN to send the server response to the client.

To enable the DHCP relay feature on the G8264CS, you need to configure the DHCP/BOOTP server IP addresses on the switch. Generally, it is best to configure the switch IP interface on the client side to match the client's subnet, and configure VLANs to separate client and server subnets. The DHCP server knows from which IP subnet the newly allocated IP address will come.

In G8264CS implementation, there is no need for primary or secondary servers. The client request is forwarded to the BOOTP servers configured on the switch. The use of two servers provide failover redundancy. However, no health checking is supported.

Use the following commands to configure the switch as a DHCP relay agent:

```
RS 8264CS(config)# ip bootp-relay server 1 <IP address>
RS 8264CS(config)# ip bootp-relay server 2 <IP address>
RS 8264CS(config)# ip bootp-relay enable
RS 8264CS(config)# show ip bootp-relay
```

Additionally, DHCP Relay functionality can be assigned on a per interface basis. Use the following commands to enable the Relay functionality:

```
RS 8264CS(config)# interface ip <Interface number>
RS 8264CS(config-ip-if)# relay
```

Chapter 22. Internet Protocol Version 6

Internet Protocol version 6 (IPv6) is a network layer protocol intended to expand the network address space. IPv6 is a robust and expandable protocol that meets the need for increased physical address space. The switch supports the following RFCs for IPv6-related features:

- RFC 1981
- RFC 2404
- RFC 2410
- RFC 2451
- RFC 2460
- RFC 2474
- RFC 2526
- RFC 2711
- RFC 2740
- RFC 3289
- RFC 3306
- RFC 3307
- RFC 3411
- RFC 3412
- RFC 3413
- RFC 3414
- RFC 3484
- RFC 3602
- RFC 3810
- RFC 3879
- RFC 4007
- RFC 4213
- RFC 4291
- RFC 4292
- RFC 4293
- RFC 4301
- RFC 4302
- RFC 4303
- RFC 4306
- RFC 4307
- RFC 4443
- RFC 4552
- RFC 4718
- RFC 4835
- RFC 4861
- RFC 4862
- RFC 5095
- RFC 5114
- RFC 5340

This chapter describes the basic configuration of IPv6 addresses and how to manage the switch via IPv6 host management.

IPv6 Limitations

The following IPv6 features are not supported in this release.

- Dynamic Host Control Protocol for IPv6 (DHCPv6)
- Border Gateway Protocol for IPv6 (BGP)
- Routing Information Protocol for IPv6 (RIPng)

Most other Lenovo Networking OS 8.2 features permit IP addresses to be configured using either IPv4 or IPv6 address formats. However, the following switch features support IPv4 only:

- Bootstrap Protocol (BOOTP) and DHCP
- RADIUS, TACACS+ and LDAP
- VMware Virtual Center (vCenter) for VMready
- Routing Information Protocol (RIP)
- Border Gateway Protocol (BGP)
- Protocol Independent Multicast (PIM)
- Virtual Router Redundancy Protocol (VRRP)
- sFlow

IPv6 Address Format

The IPv6 address is 128 bits (16 bytes) long and is represented as a sequence of eight 16-bit hex values, separated by colons.

Each IPv6 address has two parts:

- Subnet prefix representing the network to which the interface is connected
- Local identifier, either derived from the MAC address or user-configured

The preferred hexadecimal format is as follows:

```
xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx
```

Example IPv6 address:

```
FEDC:BA98:7654:BA98:FEDC:1234:ABCD:5412
```

Some addresses can contain long sequences of zeros. A single contiguous sequence of zeros can be compressed to :: (two colons). For example, consider the following IPv6 address:

```
FE80:0:0:0:2AA:FF:FA:4CA2
```

The address can be compressed as follows:

```
FE80::2AA:FF:FA:4CA2
```

Unlike IPv4, a subnet mask is not used for IPv6 addresses. IPv6 uses the subnet prefix as the network identifier. The prefix is the part of the address that indicates the bits that have fixed values or are the bits of the subnet prefix. An IPv6 prefix is written in address/prefix-length notation. For example, in the following address, 64 is the network prefix:

```
21DA:D300:0000:2F3C::/64
```

IPv6 addresses can be either user-configured or automatically configured. Automatically configured addresses always have a 64-bit subnet prefix and a 64-bit interface identifier. In most implementations, the interface identifier is derived from the switch's MAC address, using a method called EUI-64.

Most Lenovo N/OS 8.2 features permit IP addresses to be configured using either IPv4 or IPv6 address formats. Throughout this manual, *IP address* is used in places where either an IPv4 or IPv6 address is allowed. In places where only one type of address is allowed, the type (*IPv4* or *IPv6*) is specified.

IPv6 Address Types

IPv6 supports three types of addresses: unicast (one-to-one), multicast (one-to-many), and anycast (one-to-nearest). Multicast addresses replace the use of broadcast addresses.

Unicast Address

Unicast is a communication between a single host and a single receiver. Packets sent to a unicast address are delivered to the interface identified by that address. IPv6 defines the following types of unicast address:

- **Global Unicast address:** An address that can be reached and identified globally. Global Unicast addresses use the high-order bit range up to FF00, therefore all non-multicast and non-link-local addresses are considered to be global unicast. A manually configured IPv6 address must be fully specified. Autoconfigured IPv6 addresses are comprised of a prefix combined with the 64-bit EUI. RFC 4291 defines the IPv6 addressing architecture.

The interface ID must be unique within the same subnet.

- **Link-local unicast address:** An address used to communicate with a neighbor on the same link. Link-local addresses use the format FE80 : : EUI

Link-local addresses are designed to be used for addressing on a single link for purposes such as automatic address configuration, neighbor discovery, or when no routers are present.

Routers must not forward any packets with link-local source or destination addresses to other links.

Multicast

Multicast is communication between a single host and multiple receivers. Packets are sent to all interfaces identified by that address. An interface may belong to any number of multicast groups.

A multicast address (FF00 - FFFF) is an identifier for a group interface. The multicast address most often encountered is a solicited-node multicast address using prefix FF02 : : 1 : FF00 : 0000 / 104 with the low-order 24 bits of the unicast or anycast address.

The following well-known multicast addresses are pre-defined. The group IDs defined in this section are defined for explicit scope values, as follows:

FF00 : : : : : 0 through FF0F : : : : : 0

Anycast

Packets sent to an anycast address or list of addresses are delivered to the nearest interface identified by that address. Anycast is a communication between a single sender and a list of addresses.

Anycast addresses are allocated from the unicast address space, using any of the defined unicast address formats. Thus, anycast addresses are syntactically indistinguishable from unicast addresses. When a unicast address is assigned to

more than one interface, thus turning it into an anycast address, the nodes to which the address is assigned must be explicitly configured to know that it is an anycast address.

IPv6 Address Autoconfiguration

IPv6 supports the following types of address autoconfiguration:

- **Stateful address configuration**

Address configuration is based on the use of a stateful address configuration protocol, such as DHCPv6, to obtain addresses and other configuration options.

- **Stateless address configuration**

Address configuration is based on the receipt of Router Advertisement messages that contain one or more Prefix Information options.

N/OS 8.2 supports stateless address configuration.

Stateless address configuration allows hosts on a link to configure themselves with link-local addresses and with addresses derived from prefixes advertised by local routers. Even if no router is present, hosts on the same link can configure themselves with link-local addresses and communicate without manual configuration.

IPv6 Interfaces

Each IPv6 interface supports multiple IPv6 addresses. You can manually configure up to two IPv6 addresses for each interface, or you can allow the switch to use stateless autoconfiguration.

You can manually configure two IPv6 addresses for each interface, as follows:

- Initial IPv6 address is a global unicast or anycast address.

```
RS 8264CS(config)# interface ip <interface number>
RS 8264CS(config-ip-if)# ipv6 address <IPv6 address>
```

Note that you cannot configure both addresses as anycast. If you configure an anycast address on the interface you must also configure a global unicast address on that interface.

- Second IPv6 address can be a unicast or anycast address.

```
RS 8264CS(config-ip-if)# ipv6 secaddr6 <IPv6 address>
RS 8264CS(config-ip-if)# exit
```

You cannot configure an IPv4 address on an IPv6 management interface. Each interface can be configured with only one address type: either IPv4 or IPv6, but not both. When changing between IPv4 and IPv6 address formats, the prior address settings for the interface are discarded.

Each IPv6 interface can belong to only one VLAN. Each VLAN can support only one IPv6 interface. Each VLAN can support multiple IPv4 interfaces.

Use the following commands to configure the IPv6 gateway:

```
RS 8264CS(config)# ip gateway6 1 address <IPv6 address>
RS 8264CS(config)# ip gateway6 1 enable
```

IPv6 gateway 1 is reserved for IPv6 data interfaces. IPv6 gateway 4 is the default IPv6 management gateway.

Neighbor Discovery

Neighbor Discovery Overview

The switch uses Neighbor Discovery protocol (ND) to gather information about other router and host nodes, including the IPv6 addresses. Host nodes use ND to configure their interfaces and perform health detection. ND allows each node to determine the link-layer addresses of neighboring nodes, and to keep track of each neighbor's information. A neighboring node is a host or a router that is linked directly to the switch. The switch supports Neighbor Discovery as described in RFC 4861.

Neighbor Discover messages allow network nodes to exchange information, as follows:

- *Neighbor Solicitations* allow a node to discover information about other nodes.
- *Neighbor Advertisements* are sent in response to Neighbor Solicitations. The Neighbor Advertisement contains information required by nodes to determine the link-layer address of the sender, and the sender's role on the network.
- IPv6 hosts use *Router Solicitations* to discover IPv6 routers. When a router receives a Router Solicitation, it responds immediately to the host.
- Routers uses *Router Advertisements* to announce its presence on the network, and to provide its address prefix to neighbor devices. IPv6 hosts listen for Router Advertisements, and uses the information to build a list of default routers. Each host uses this information to perform autoconfiguration of IPv6 addresses.
- *Redirect messages* are sent by IPv6 routers to inform hosts of a better first-hop address for a specific destination. Redirect messages are only sent by routers for unicast traffic, are only unicast to originating hosts, and are only processed by hosts.

ND configuration for general advertisements, flags, and interval settings, as well as for defining prefix profiles for router advertisements, is performed on a per-interface basis using the following command path:

```
RS 8264CS(config)# interface ip <interface number>  
RS 8264CS(config-ip-if)# [no] ipv6 nd ?  
RS 8264CS(config-ip-if)# exit
```

To add or remove entries in the static neighbor cache, use the following command path:

```
RS 8264CS(config)# [no] ip neighbors ?
```

Host vs. Router

Each IPv6 interface can be configured as a router node or a host node, as follows:

- A router node's IP address is configured manually. Router nodes can send Router Advertisements.
- A host node's IP address is autoconfigured. Host nodes listen for Router Advertisements that convey information about devices on the network.

Note: When IP forwarding is turned on, all IPv6 interfaces configured on the switch can forward packets.

You can configure each IPv6 interface as either a host node or a router node. You can manually assign an IPv6 address to an interface in host mode, or the interface can be assigned an IPv6 address by an upstream router, using information from router advertisements to perform stateless auto-configuration.

To set an interface to host mode, use the following command:

```
RS 8264CS(config)# interface ip <interface number>  
RS 8264CS(config-ip-if)# ip6host  
RS 8264CS(config-ip-if)# exit
```

The G8264CS supports up to 1156 IPv6 routes.

Supported Applications

The following applications have been enhanced to provide IPv6 support.

- **Ping**

The **ping** command supports IPv6 addresses. Use the following format to ping an IPv6 address:

```
ping <host name>| <IPv6 address> [<tries (0-4294967295)>] [data-port]  
[mgmt-port]
```

- **Traceroute**

The **traceroute** command supports IPv6 addresses (but not link-local addresses).

Use the following format to perform a traceroute to an IPv6 address:

```
traceroute <host name>| <IPv6 address> [<max-hops (1-32)>  
[<msec delay (1-4294967295)>]]
```

- **Telnet server**

The **telnet** command supports IPv6 addresses (but not link-local addresses).

Use the following format to Telnet into an IPv6 interface on the switch:

```
telnet <host name>| <IPv6 address> [<port>]
```

- **Telnet client**

The **telnet** command supports IPv6 addresses (but not link-local addresses).

Use the following format to Telnet to an IPv6 address:

```
telnet <host name>| <IPv6 address> [<port>]
```

- **HTTP/HTTPS**

The HTTP/HTTPS servers support both IPv4 and IPv6 connections.

- **SSH**

Secure Shell (SSH) connections over IPv6 are supported (but not link-local addresses). The following syntax is required from the client:

```
ssh -u <IPv6 address>
```

Example:

```
ssh -u 2001:2:3:4:0:0:0:142
```

- **TFTP**

The TFTP commands support both IPv4 and IPv6 addresses. Link-local addresses are not supported.

- **FTP**

The FTP commands support both IPv4 and IPv6 addresses. Link-local addresses are not supported.

- **DNS client**

DNS commands support both IPv4 and IPv6 addresses. Link-local addresses are not supported. Use the following command to specify the type of DNS query to be sent first:

```
RS 8264CS(config)# ip dns ipv6 request-version {ipv4|ipv6}
```

If you set the request version to `ipv4`, the DNS application sends an `A` query first, to resolve the hostname with an IPv4 address. If no `A` record is found for that hostname (no IPv4 address for that hostname) an `AAAA` query is sent to resolve the hostname with a IPv6 address.

If you set the request version to `ipv6`, the DNS application sends an `AAAA` query first, to resolve the hostname with an IPv6 address. If no `AAAA` record is found for that hostname (no IPv6 address for that hostname) an `A` query is sent to resolve the hostname with an IPv4 address.

Configuration Guidelines

When you configure an interface for IPv6, consider the following guidelines:

- Support for subnet router anycast addresses is not available.
- A single interface can accept either IPv4 or IPv6 addresses, but not both IPv4 and IPv6 addresses.
- A single interface can accept multiple IPv6 addresses.
- A single interface can accept only one IPv4 address.
- If you change the IPv6 address of a configured interface to an IPv4 address, all IPv6 settings are deleted.
- A single VLAN can support only one IPv6 interface.
- Health checks are not supported for IPv6 gateways.
- IPv6 interfaces support Path MTU Discovery. The CPU's MTU is fixed at 1500 bytes.
- Support for jumbo frames (1,500 to 9,216 byte MTUs) is limited. Any jumbo frames intended for the CPU must be fragmented by the remote node. The switch can re-assemble fragmented packets up to 9k. It can also fragment and transmit jumbo packets received from higher layers.

IPv6 Configuration Examples

This section provides steps to configure IPv6 on the switch.

IPv6 Example 1

The following example uses IPv6 host mode to autoconfigure an IPv6 address for the interface. By default, the interface is assigned to VLAN 1.

1. Enable IPv6 host mode on an interface.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip6host
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Configure the IPv6 default gateway.

```
RS 8264CS(config)# ip gateway6 1 address
2001:BA98:7654:BA98:FEDC:1234:ABCD:5412
RS 8264CS(config)# ip gateway6 1 enable
```

3. Verify the interface address.

```
RS 8264CS(config)# show interface ip 2
```

IPv6 Example 2

Use the following example to manually configure IPv6 on an interface.

1. Assign an IPv6 address and prefix length to the interface.

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ipv6 address
2001:BA98:7654:BA98:FEDC:1234:ABCD:5214
RS 8264CS(config-ip-if)# ipv6 prefixlen 64
RS 8264CS(config-ip-if)# ipv6 seccaddr6 2003::1 32
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

The secondary IPv6 address is compressed, and the prefix length is 32.

2. Configure the IPv6 default gateway.

```
RS 8264CS(config)# ip gateway6 1 address
2001:BA98:7654:BA98:FEDC:1234:ABCD:5412
RS 8264CS(config)# ip gateway6 1 enable
```

3. Configure router advertisements for the interface (optional)

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# no ipv6 nd suppress-ra
```

4. Verify the configuration.

```
RS 8264CS(config-ip-if)# show layer3
```

Chapter 23. IPsec with IPv6

Internet Protocol Security (IPsec) is a protocol suite for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet of a communication session. IPsec also includes protocols for establishing mutual authentication between agents at the beginning of the session and negotiation of cryptographic keys to be used during the session.

Since IPsec was implemented in conjunction with IPv6, all implementations of IPv6 must contain IPsec. To support the National Institute of Standards and Technology (NIST) recommendations for IPv6 implementations, Lenovo Networking OS IPv6 feature compliance has been extended to include the following IETF RFCs, with an emphasis on IP Security (IPsec) and Internet Key Exchange version 2, and authentication/confidentiality for OSPFv3:

- RFC 4301 for IPv6 security
- RFC 4302 for the IPv6 Authentication Header
- RFCs 2404, 2410, 2451, 3602, and 4303 for IPv6 Encapsulating Security Payload (ESP), including NULL encryption, CBC-mode 3DES and AES ciphers, and HMAC-SHA-1-96.
- RFCs 4306, 4307, 4718, and 4835 for IKEv2 and cryptography
- RFC 4552 for OSPFv3 IPv6 authentication/confidentiality
- RFC 5114 for Diffie-Hellman groups

Note: This implementation of IPsec supports DH group 24.

The following topics are discussed in this chapter:

- [“IPsec Protocols” on page 338](#)
- [“Using IPsec with the RackSwitch G8264CS” on page 339](#)

IPsec Protocols

The Lenovo N/OS implementation of IPsec supports the following protocols:

- Authentication Header (AH)
AHs provide connectionless integrity and data origin authentication for IP packets, and provide protection against replay attacks. In IPv6, the AH protects the AH itself, the Destination Options extension header after the AH, and the IP payload. It also protects the fixed IPv6 header and all extension headers before the AH, except for the mutable fields DSCP, ECN, Flow Label, and Hop Limit. AH is defined in RFC 4302.
- Encapsulating Security Payload (ESP)
ESPs provide confidentiality, data origin authentication, integrity, an anti-replay service (a form of partial sequence integrity), and some traffic flow confidentiality. ESPs may be applied alone or in combination with an AH. ESP is defined in RFC 4303.
- Internet Key Exchange Version 2 (IKEv2)
IKEv2 is used for mutual authentication between two network elements. An IKE establishes a security association (SA) that includes shared secret information to efficiently establish SAs for ESPs and AHs, and a set of cryptographic algorithms to be used by the SAs to protect the associated traffic. IKEv2 is defined in RFC 4306.

Using IKEv2 as the foundation, IPsec supports ESP for encryption and/or authentication, and/or AH for authentication of the remote partner.

Both ESP and AH rely on security associations. A security association (SA) is the bundle of algorithms and parameters (such as keys) that encrypt and authenticate a particular flow in one direction.

Using IPsec with the RackSwitch G8264CS

IPsec supports the fragmentation and reassembly of IP packets that occurs when data goes to and comes from an external device. The RackSwitch G8264CS acts as an end node that processes any fragmentation and reassembly of packets but does not forward the IPsec traffic. The IKEv2 key must be authenticated before you can use IPsec.

The security protocol for the session key is either ESP or AH. Outgoing packets are labeled with the SA SPI (Security Parameter Index), which the remote device will use in its verification and decryption process.

Every outgoing IPv6 packet is checked against the IPsec policies in force. For each outbound packet, after the packet is encrypted, the software compares the packet size with the MTU size that it either obtains from the default minimum maximum transmission unit (MTU) size (1500) or from path MTU discovery. If the packet size is larger than the MTU size, the receiver drops the packet and sends a message containing the MTU size to the sender. The sender then fragments the packet into smaller pieces and retransmits them using the correct MTU size.

The maximum traffic load for each IPsec packet is limited to the following:

- IKEv2 SAs: 5
- IPsec SAs: 10 (5 SAs in each direction)
- SPDs: 20 (10 policies in each direction)

IPsec is implemented as a software cryptography engine designed for handling control traffic, such as network management. IPsec is not designed for handling data traffic, such as a VPN.

Setting up Authentication

Before you can use IPsec, you need to have key policy authentication in place. There are two types of key policy authentication:

- Preshared key (default)

The parties agree on a shared, secret key that is used for authentication in an IPsec policy. During security negotiation, information is encrypted before transmission by using a session key created by using a Diffie-Hellman calculation and the shared, secret key. Information is decrypted on the receiving end using the same key. One IPsec peer authenticates the other peer's packet by decryption and verification of the hash inside the packet (the hash inside the packet is a hash of the preshared key). If authentication fails, the packet is discarded.

- Digital certificate (using RSA algorithms)

The peer being validated must hold a digital certificate signed by a trusted Certificate Authority and the private key for that digital certificate. The side performing the authentication only needs a copy of the trusted certificate authorities digital certificate. During IKEv2 authentication, the side being validated sends a copy of the digital certificate and a hash value signed using the private key. The certificate can be either generated or imported.

Note: During the IKEv2 negotiation phase, the digital certificate takes precedence over the preshared key.

Creating an IKEv2 Proposal

With IKEv2, a single policy can have multiple encryption and authentication types, as well as multiple integrity algorithms.

To create an IKEv2 proposal:

1. Enter IKEv2 proposal mode.

```
RS 8264CS(config)# ikev2 proposal
```

2. Set the DES encryption algorithm.

```
RS 8264CS(config-ikev2-prop)# encryption 3des|aes-cbc (default: 3des)
```

3. Set the authentication integrity algorithm type.

```
RS 8264CS(config-ikev2-prop)# integrity sha1 (default: sha1)
```

4. Set the Diffie-Hellman group.

```
RS 8264CS(config-ikev2-prop)# group 24 (default: 24)
```

Importing an IKEv2 Digital Certificate

To import an IKEv2 digital certificate for authentication:

1. Import the CA certificate file.

```
RS 8264CS(config)# copy tftp ca-cert address <hostname or IPv4 address>

Source file name: <path and filename of CA certificate file>
Port type ["DATA"/"MGT"]: >
Confirm download operation [y/n]: y
```

2. Import the host key file.

```
RS 8264CS(config)# copy tftp host-key address <hostname or IPv4 address>

Source file name: <path and filename of host private key file>
Port type ["DATA"/"MGT"]: >
Confirm download operation [y/n]: y
```

3. Import the host certificate file.

```
RS 8264CS(config)# copy tftp host-cert address <hostname or IPv4 address>

Source file name: <path and filename of host certificate file>
Port type ["DATA"/"MGT"]: >
Confirm download operation [y/n]: y
```

Note: When prompted for the port to use for download the file, if you used a management port to connect the switch to the server, enter **mgmt**, otherwise enter **data**.

Generating an IKEv2 Digital Certificate

To create an IKEv2 digital certificate for authentication:

1. Create an HTTPS certificate defining the information you want to be used in the various fields.

```
RS 8264CS(config)# access https generate-certificate
Country Name (2 letter code) [US]: <country code>
State or Province Name (full name) [CA]: <state>
Locality Name (eg, city) [Santa Clara]: <city>
Organization Name (eg, company) [Lenovo]: <company>
Organizational Unit Name (eg, section) [Engineering]: <org. unit>
Common Name (eg, YOUR name) []: <your current IP address>
Email (eg, email address) []: <email address>
Confirm generating certificate? [y/n]: y
Generating certificate. Please wait (approx 30 seconds)
restarting SSL agent
```

2. Save the HTTPS certificate.

The certificate is valid only until the switch is rebooted. To save the certificate so that it is retained beyond reboot or power cycles, use the following command:

```
RS 8264CS(config)# access https save-certificate
```

3. Enable IKEv2 RSA-signature authentication:

```
RS 8264CS(config)# access https enable
```

Enabling IKEv2 Preshared Key Authentication

To set up IKEv2 preshared key authentication:

1. Enter the local preshared key.

```
RS 8264CS(config)# ikev2 preshare-key local <preshared key, a string of 1-256 chars>
```

2. If asymmetric authentication is supported, enter the remote key:

```
RS 8264CS(config)# ikev2 preshare-key remote <preshared key> <IPv6 host>
```

where the following parameters are used:

- *preshared key* A string of 1-256 characters
- *IPv6 host* An IPv6-format host, such as "3000::1"

3. Set up the IKEv2 identification type by entering *one* of the following commands:

```
RS 8264CS(config)# ikev2 identity local address (use an IPv6 address)
RS 8264CS(config)# ikev2 identity local email <email address>
RS 8264CS(config)# ikev2 identity local fqdn <domain name>
```

To disable IKEv2 RSA-signature authentication method and enable preshared key authentication, enter:

```
RS 8264CS(config)# access https disable
```

Setting Up a Key Policy

When configuring IPsec, you must define a key policy. This key policy can be either manual or dynamic. Either way, configuring a policy involves the following steps:

- Create a transform set— This defines which encryption and authentication algorithms are used.
 - Create a traffic selector— This describes the packets to which the policy applies.
 - Establish an IPsec policy.
 - Apply the policy.
1. To define which encryption and authentication algorithms are used, create a transform set:

```
RS 8264CS(config)# ipsec transform-set <transform ID> <encryption method> <integrity algorithm> <AH authentication algorithm>
```

where the following parameters are used:

- *transform ID* A number from 1-10
- *encryption method* One of the following: **esp-3des** | **esp-aes-cbc** | **esp-null**
- *integrity algorithm* One of the following: **esp-sha1**
- *AH authentication algorithm* One of the following: **ah-sha1**

2. Decide whether to use tunnel or transport mode. The default mode is transport.

```
RS 8264CS(config)# ipsec transform-set tunnel|transport
```

3. To describe the packets to which this policy applies, create a traffic selector using the following command:

```
RS 8264CS(config)# ipsec traffic-selector <traffic selector number> permit|deny any|icmp <type/any> |tcp > <source IP address/any> <destination IP address/any> [<prefix length>]
```

where the following parameters are used:

- *traffic selector number* an integer from 1-10
- **permit|deny** whether or not to permit IPsec encryption of traffic that meets the criteria specified in this command
- **any** apply the selector to any type of traffic
- **icmp <type>|any** only apply the selector only to ICMP traffic of the specified *type* (an integer from 1-255) or to any ICMP traffic
- **tcp** only apply the selector to TCP traffic
- *source IP address|any* the source IP address in IPv6 format or “any” source

- *destination IP address* | **any** the destination IP address in IPv6 format or “any” destination
- *prefix length* (Optional) the length of the destination IPv6 prefix; an integer from 1-128

Permitted traffic that matches the policy in force is encrypted, while denied traffic that matches the policy in force is dropped. Traffic that does not match the policy bypasses IPsec and passes through *clear* (unencrypted).

4. Choose whether to use a manual or a dynamic policy.

Using a Manual Key Policy

A manual policy involves configuring policy and manual SA entries for local and remote peers.

To configure a manual key policy, you need:

- The IP address of the peer in IPv6 format (for example, “3000::1”).
- Inbound/Outbound session keys for the security protocols.

You can then assign the policy to an interface. The peer represents the other end of the security association. The security protocol for the session key can be either ESP or AH.

To create and configure a manual policy:

1. Enter a manual policy to configure.

```
RS 8264CS(config)#ipsec manual-policy <policy number>
```

2. Configure the policy.

```
RS 8264CS(config-ipsec-manual)#peer <peer's IPv6 address>
RS 8264CS(config-ipsec-manual)#traffic-selector <IPsec traffic selector>
RS 8264CS(config-ipsec-manual)#transform-set <IPsec transform set>
RS 8264CS(config-ipsec-manual)#in-ah auth-key <inbound AH IPsec key>
RS 8264CS(config-ipsec-manual)#in-ah auth-spi <inbound AH IPsec SPI>
RS 8264CS(config-ipsec-manual)#in-esp cipher-key <inbound ESP cipher key>
RS 8264CS(config-ipsec-manual)#in-esp auth-spi <inbound ESP SPI>
RS 8264CS(config-ipsec-manual)#in-esp auth-key <inbound ESP authenticator key>
RS 8264CS(config-ipsec-manual)#out-ah auth-key <outbound AH IPsec key>
RS 8264CS(config-ipsec-manual)#out-ah auth-spi <outbound AH IPsec SPI>
RS 8264CS(config-ipsec-manual)#out-esp cipher-key <outbound ESP cipher key>
RS 8264CS(config-ipsec-manual)#out-esp auth-spi <outbound ESP SPI>
RS 8264CS(config-ipsec-manual)#out-esp auth-key <outbound ESP authenticator key>
```

where the following parameters are used:

- *peer's IPv6 address* The IPv6 address of the peer (for example, 3000::1)
- *IPsec traffic-selector* A number from 1-10
- *IPsec of transform-set* A number from 1-10
- *inbound AH IPsec key* The inbound AH key code, in hexadecimal
- *inbound AH IPsec SPI* A number from 256-4294967295

- *inbound ESP cipher key* The inbound ESP key code, in hexadecimal
- *inbound ESP SPI* A number from 256-4294967295
- *inbound ESP authenticator key* The inbound ESP authenticator key code, in hexadecimal
- *outbound AH IPsec key* The outbound AH key code, in hexadecimal
- *outbound AH IPsec SPI* A number from 256-4294967295
- *outbound ESP cipher key* The outbound ESP key code, in hexadecimal
- *outbound ESP SPI* A number from 256-4294967295
- *outbound ESP authenticator key* The outbound ESP authenticator key code, in hexadecimal

Notes:

- When configuring a manual policy ESP, the ESP authenticator key is optional.
 - If using third-party switches, the IPsec manual policy session key must be of fixed length as follows:
 - For AH key: SHA1 is 20 bytes; MD5 is 16 bytes
 - For ESP cipher key: 3DES is 24 bytes; AES-cbc is 24 bytes; DES is 8 bytes
 - For ESP auth key: SHA1 is 20 bytes; MD5 is 16 bytes
3. After you configure the IPsec policy, you need to apply it to the interface to enforce the security policies on that interface and save it to keep it in place after a reboot. To accomplish this, enter:

```
RS 8264CS(config-ip)#interface ip <IP interface number, 1-128>
RS 8264CS(config-ip-if)#address <IPv6 address>
RS 8264CS(config-ip-if)#ipsec manual-policy <policy index, 1-10>
RS 8264CS(config-ip-if)#enable (enable the IP interface)
RS 8264CS#write (save the current configuration)
```

Using a Dynamic Key Policy

When you use a dynamic key policy, the first packet triggers IKE and sets the IPsec SA and IKEv2 SA. The initial packet negotiation also determines the lifetime of the algorithm, or how long it stays in effect. When the key expires, a new key is automatically created. This helps prevent break-ins.

To configure a dynamic key policy:

1. Choose a dynamic policy to configure.

```
RS 8264CS(config)#ipsec dynamic-policy <policy number>
```

2. Configure the policy.

```
RS 8264CS(config-ipsec-dynamic)#peer <peer's IPv6 address>  
RS 8264CS(config-ipsec-dynamic)#traffic-selector <index of traffic selector>  
RS 8264CS(config-ipsec-dynamic)#transform-set <index of transform set>  
RS 8264CS(config-ipsec-dynamic)#sa-lifetime <SA lifetime, in seconds>  
RS 8264CS(config-ipsec-dynamic)#pfs enable|disable
```

where the following parameters are used:

- *peer's IPv6 address* The IPv6 address of the peer (for example, 3000::1)
- *index of traffic-selector* A number from 1-10
- *index of transform-set* A number from 1-10
- *SA lifetime, in seconds* The length of time the SA is to remain in effect; an integer from 120-86400
- **pfs enable|disable** Whether to enable or disable the perfect forward security feature. The default is **disable**.

Note: In a dynamic policy, the AH and ESP keys are created by IKEv2.

3. After you configure the IPsec policy, you need to apply it to the interface to enforce the security policies on that interface and save it to keep it in place after a reboot. To accomplish this, enter:

```
RS 8264CS(config-ip)#interface ip <IP interface number, 1-128>  
RS 8264CS(config-ip-if)#address <IPv6 address>  
RS 8264CS(config-ip-if)#ipsec dynamic-policy <policy index, 1-10>  
RS 8264CS(config-ip-if)#enable (enable the IP interface)  
RS 8264CS#write (save the current configuration)
```

Chapter 24. Routing Information Protocol

In a routed environment, routers communicate with one another to keep track of available routes. Routers can learn about available routes dynamically using the Routing Information Protocol (RIP). Lenovo Networking OS software supports RIP version 1 (RIPv1) and RIP version 2 (RIPv2) for exchanging TCP/IPv4 route information with other routers.

Note: Lenovo N/OS 8.2 does not support IPv6 for RIP.

Distance Vector Protocol

RIP is known as a distance vector protocol. The vector is the network number and next hop, and the distance is the metric associated with the network number. RIP identifies network reachability based on metric, and metric is defined as hop count. One hop is considered to be the distance from one switch to the next, which typically is 1.

When a switch receives a routing update that contains a new or changed destination network entry, the switch adds 1 to the metric value indicated in the update and enters the network in the routing table. The IPv4 address of the sender is used as the next hop.

Stability

RIP includes a number of other stability features that are common to many routing protocols. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. The network destination network is considered unreachable if increasing the metric value by 1 causes the metric to be 16 (that is infinity). This limits the maximum diameter of a RIP network to less than 16 hops.

RIP is often used in stub networks and in small autonomous systems that do not have many redundant paths.

Routing Updates

RIP sends routing-update messages at regular intervals and when the network topology changes. Each router “advertises” routing information by sending a routing information update every 30 seconds. If a router doesn’t receive an update from another router for 180 seconds, those routes provided by that router are declared invalid. The routes are removed from the routing table, but they remain in the RIP routes table. After another 120 seconds without receiving an update for those routes, the routes are removed from respective regular updates.

When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP routers maintain only the best route (the route with the lowest metric value) to a destination.

For more information, see the Configuration section, Routing Information Protocol Configuration in the *Lenovo Networking OS Command Reference*.

RIPv1

RIP version 1 use broadcast User Datagram Protocol (UDP) data packets for the regular routing updates. The main disadvantage is that the routing updates do not carry subnet mask information. Hence, the router cannot determine whether the route is a subnet route or a host route. It is of limited usage after the introduction of RIPv2. For more information about RIPv1 and RIPv2, refer to RFC 1058 and RFC 2453.

RIPv2

RIPv2 is the most popular and preferred configuration for most networks. RIPv2 expands the amount of useful information carried in RIP messages and provides a measure of security. For a detailed explanation of RIPv2, refer to RFC 1723 and RFC 2453.

RIPv2 improves efficiency by using multicast UDP (address 224.0.0.9) data packets for regular routing updates. Subnet mask information is provided in the routing updates. A security option is added for authenticating routing updates, by using a shared password. N/OS supports using clear password for RIPv2.

RIPv2 in RIPv1 Compatibility Mode

N/OS allows you to configure RIPv2 in RIPv1 compatibility mode, for using both RIPv2 and RIPv1 routers within a network. In this mode, the regular routing updates use broadcast UDP data packet to allow RIPv1 routers to receive those packets. With RIPv1 routers as recipients, the routing updates have to carry natural or host mask. Hence, it is not a recommended configuration for most network topologies.

Note: When using both RIPv1 and RIPv2 within a network, use a single subnet mask throughout the network.

RIP Features

N/OS provides the following features to support RIPv1 and RIPv2:

Poison

Simple split horizon in RIP scheme omits routes learned from one neighbor in updates sent to that neighbor. That is the most common configuration used in RIP, that is setting this Poison to DISABLE. Split horizon with poisoned reverse includes such routes in updates, but sets their metrics to 16. The disadvantage of using this feature is the increase of size in the routing updates.

Triggered Updates

Triggered updates are an attempt to speed up convergence. When Triggered Updates is enabled, whenever a router changes the metric for a route, it sends update messages almost immediately, without waiting for the regular update interval. It is recommended to enable Triggered Updates.

Multicast

RIPv2 messages use IPv4 multicast address (224.0.0.9) for periodic broadcasts. Multicast RIPv2 announcements are not processed by RIPv1 routers. IGMP is not needed since these are inter-router messages which are not forwarded.

To configure RIPv2 in RIPv1 compatibility mode, set multicast to `disable`, and set version to `both`.

Default

The RIP router can listen and supply a default route, usually represented as IPv4 0.0.0.0 in the routing table. When a router does not have an explicit route to a destination network in its routing table, it uses the default route to forward those packets.

Metric

The metric field contains a configurable value between 1 and 15 (inclusive) which specifies the current metric for the interface. The metric value typically indicates the total number of hops to the destination. The metric value of 16 represents an unreachable destination.

Authentication

RIPv2 authentication uses plaintext password for authentication. If configured using Authentication password, then it is necessary to enter an authentication key value.

The following method is used to authenticate an RIP message:

- If the router is not configured to authenticate RIPv2 messages, then RIPv1 and unauthenticated RIPv2 messages are accepted; authenticated RIPv2 messages are discarded.
- If the router is configured to authenticate RIPv2 messages, then RIPv1 messages and RIPv2 messages which pass authentication testing are accepted; unauthenticated and failed authentication RIPv2 messages are discarded.

For maximum security, RIPv1 messages are ignored when authentication is enabled; otherwise, the routing information from authenticated messages is propagated by RIPv1 routers in an unauthenticated manner.

RIP Configuration Example

The following is an example of RIP configuration.

Note: An interface RIP disabled uses all the default values of the RIP, no matter how the RIP parameters are configured for that interface. RIP sends out RIP regular updates to include an UP interface, but not a DOWN interface.

1. Add VLANs for routing interfaces.

```
>> (config)# vlan 2
>> (config-vlan)# exit
>> (config)# interface port 2
>> (config-if)# switchport mode trunk
>> (config-if)# switchport trunk allowed vlan add 2
>> (config-if)# exit

Port 2 is an UNTAGGED port and its current PVID is 1.
Confirm changing PVID from 1 to 2 [y/n]: y
>> (config)# vlan 3
>> (config-vlan)# exit
>> (config)# interface port 3
>> (config-if)# switchport mode trunk
>> (config-if)# switchport trunk allowed vlan add 3
>> (config-if)# exit
Port 3 is an UNTAGGED port and its current PVID is 1.
Confirm changing PVID from 1 to 3 [y/n]: y
```

2. Add IP interfaces with IPv4 addresses to VLANs.

```
>> # interface ip 2
>> (config-ip-if)# enable
>> (config-ip-if)# ip address 102.1.1.1
>> (config-ip-if)# vlan 2
>> (config-ip-if)# exit
>> # interface ip 3
>> (config-ip-if)# enable
>> (config-ip-if)# ip address 103.1.1.1
>> (config-ip-if)# vlan 3
```

3. Turn on RIP globally and enable RIP for each interface.

```
>> # router rip
>> (config-router-rip)# enable
>> (config-router-rip)# exit
>> # interface ip 2
>> (config-ip-if)# ip rip enable
>> (config-ip-if)# exit
>> # interface ip 3
>> (config-ip-if)# ip rip enable
>> (config-ip-if)# exit
```

Use the following command to check the current valid routes in the routing table of the switch:

```
>> # show ip route
```

For those RIP routes learned within the garbage collection period, that are routes phasing out of the routing table with metric 16, use the following command:

```
>> # show ip rip routes
```

Locally configured static routes do not appear in the RIP Routes table.

Chapter 25. Internet Group Management Protocol

Internet Group Management Protocol (IGMP) is used by IPv4 Multicast routers (Mrouters) to learn about the existence of host group members on their directly attached subnet. The IPv4 Mrouters get this information by broadcasting IGMP Membership Queries and listening for IPv4 hosts reporting their host group memberships. This process is used to set up a client/server relationship between an IPv4 multicast source that provides the data streams and the clients that want to receive the data. The switch supports three versions of IGMP:

- IGMPv1: Defines the method for hosts to join a multicast group. However, this version does not define the method for hosts to leave a multicast group. See RFC 1112 for details.
- IGMPv2: Adds the ability for a host to signal its desire to leave a multicast group. See RFC 2236 for details.
- IGMPv3: Adds support for source filtering by which a host can report interest in receiving packets only from specific source addresses, or from all but specific source addresses, sent to a particular multicast address. See RFC 3376 for details.

The G8264CS can perform IGMP Snooping, and connect to static Mrouters. The G8264CS can act as a Querier, and participate in the IGMP Querier election process.

The following topics are discussed in this chapter:

- [“IGMP Terms” on page 354](#)
- [“How IGMP Works” on page 355](#)
- [“IGMP Capacity and Default Values” on page 356](#)
- [“IGMP Snooping” on page 357](#)
- [“IGMP Relay” on page 370](#)
- [“Additional IGMP Features” on page 379](#)

IGMP Terms

The following are commonly used IGMP terms:

- Multicast traffic: Flow of data from one source to multiple destinations.
- Group: A multicast stream to which a host can join. Multicast groups have IP addresses in the range: 224.0.1.0 to 239.255.255.255.
- IGMP Querier: A router or switch in the subnet that generates *Membership Queries*.
- IGMP Snooper: A Layer 3 device that forwards multicast traffic only to hosts that are interested in receiving multicast data. This device can be a router or a Layer 3 switch.
- Multicast Router: A router configured to make routing decisions for multicast traffic. The router identifies the type of packet received (unicast or multicast) and forwards the packet to the intended destination.
- IGMP Proxy: A device that filters Join messages and Leave messages sent upstream to the Mrouter to reduce the load on the Mrouter.
- Membership Report: A report sent by the host that indicates an interest in receiving multicast traffic from a multicast group.
- Leave: A message sent by the host when it wants to leave a multicast group.
- FastLeave: A process by which the switch stops forwarding multicast traffic to a port as soon as it receives a Leave message.
- Membership Query: Message sent by the Querier to verify if hosts are listening to a group.
- General Query: A *Membership Query* sent to all hosts. The Group address field for general queries is 0.0.0.0 and the destination address is 224.0.0.1.
- Group-specific Query: A *Membership Query* sent to all hosts in a multicast group.

How IGMP Works

When IGMP is not configured, switches forward multicast traffic through all ports, increasing network load. When IGMPv2 is configured on a switch, multicast traffic flows as follows:

- A server sends multicast traffic to a multicast group.
- The Mrouter sends *Membership Queries* to the switch, which forwards them to all ports in a given VLAN.
- Hosts respond with *Membership Reports* if they want to join a group. The switch forwards these reports to the Mrouter.
- The switch forwards multicast traffic only to hosts that have joined a group.
- The Mrouter periodically sends *Membership Queries* to ensure that a host wants to continue receiving multicast traffic. If a host does not respond, the IGMP Snooper stops sending traffic to the host.
- The host can initiate the Leave process by sending an IGMP Leave packet to the IGMP Snooper.
- When a host sends an IGMPv2 Leave packet, the IGMP Snooper queries to find out if any other host connected to the port is interested in receiving the multicast traffic. If it does not receive a Join message in response, the IGMP Snooper removes the group entry and passes on the information to the Mrouter.

The G8264CS supports the following:

- IGMP version 1, 2, and 3
- 128 static Mrouters and 128 dynamic Mrouters

Note: Unknown multicast traffic is sent to all ports if the flood option is enabled and no Membership Report was learned for that specific IGMP group. If the flood option is disabled, unknown multicast traffic is discarded if no hosts or Mrouters are learned on a switch.

To enable or disable IGMP flood, use the following command:

```
RS 8264CS(config)# vlan <vlan ID>  
RS 8264CS(config-vlan)# [no] flood
```

IGMP Capacity and Default Values

The following table lists the maximum and minimum values of the G8264CS variables.

Table 32. *G8264CS Capacity Table*

Variable	Maximum
IGMP Entries - Snoop	3072
IGMP Entries - Relay	1000
VLANs - Snoop	1024
VLANs - Relay	8
Static Mrouters	128
Dynamic Mrouters	128
Number of IGMP Filters	16
IPMC Groups (IGMP Relay)	1000

The following table lists the default settings for IGMP features and variables.

Table 33. *IGMP Default Configuration Settings*

Field	Default Value
Global IGMP State	Disabled
IGMP Querier	Disabled
IGMP Snooping	Disabled
IGMP Filtering	Disabled
IP Multicast (IPMC) Flood	Enabled
IGMP FastLeave	Disabled for all VLANs
IGMP Mrouter Timeout	255 Seconds
IGMP Report Timeout Variable	10 Seconds
IGMP Query-Interval Variable	125 Seconds
IGMP Robustness Variable	2
IGMPv3	Disabled
IGMPv3 number of sources	8 (The switch processes only the first eight sources listed in the IGMPv3 group record.) Valid range: 1 - 64
IGMPv3 - allow v1v2 Snooping	Enabled

IGMP Snooping

IGMP Snooping allows a switch to listen to the IGMP conversation between hosts and Mrouters. By default, a switch floods multicast traffic to all ports in a broadcast domain. With IGMP Snooping enabled, the switch learns the ports interested in receiving multicast data and forwards it only to those ports. IGMP Snooping conserves network resources.

The switch can sense IGMP *Membership Reports* from attached hosts and acts as a proxy to set up a dedicated path between the requesting host and a local IPv4 Mrouter. After the path is established, the switch blocks the IPv4 multicast stream from flowing through any port that does not connect to a host member, thus conserving bandwidth.

IGMP Querier

For IGMP Snooping to function, you must have an Mrouter on the network that generates IGMP Query packets. Enabling the IGMP Querier feature on the switch allows it to participate in the Querier election process. If the switch is elected as the Querier, it will send IGMP Query packets for the LAN segment.

Querier Election

If multiple Mrouters exist on the network, only one can be configured as a Querier. The Mrouters elect the one with the lowest source IPv4 address or MAC address as the Querier. The Querier performs all periodic membership queries. All other Mrouters (non-Queriers) do not send IGMP Query packets.

Note: When IGMP Querier is enabled on a VLAN, the switch performs the role of an IGMP Querier only if it meets the IGMP Querier election criteria.

Each time the Querier switch sends an IGMP Query packet, it initializes a *general query timer*. If a Querier receives a General Query packet from an Mrouter with a lower IP address or MAC address, it transitions to a non-Querier state and initializes an *other querier present timer*. When this timer expires, the Mrouter transitions back to the Querier state and sends a General Query packet.

Follow this procedure to configure IGMP Querier.

1. Enable IGMP and configure the source IPv4 address for IGMP Querier on a VLAN.

```
RS 8264CS(config)# ip igmp enable
RS 8264CS(config)# ip igmp querier vlan 2 source-ip 10.10.10.1
```

2. Enable IGMP Querier on the VLAN.

```
RS 8264CS(config)# ip igmp querier vlan 2 enable
```

3. Configure the querier election type and define the address.

```
RS 8264CS(config)# ip igmp querier vlan 2 election-type ipv4
```

4. Verify the configuration.

```
RS 8264CS# show ip igmp querier vlan 2

Current IGMP snooping Querier information:
IGMP Querier information for vlan 2:
Other IGMP querier - none
Switch-querier enabled, current state: Querier
Switch-querier type: Ipv4, address 10.10.10.1,
Switch-querier general query interval: 125 secs,
Switch-querier max-response interval: 100 'tenths of secs',
Switch-querier startup interval: 31 secs, count: 2
Switch-querier robustness: 2
IGMP configured version is v3
IGMP Operating version is v3
```

IGMP Groups

One IGMP entry is allocated for each unique join request, based on the VLAN and IGMP group address. If multiple ports join the same IGMP group using the same VLAN, only a single IGMP entry is used.

IGMPv3 Snooping

IGMPv3 includes new Membership Report messages that extend IGMP functionality. The switch provides snooping capability for all types of IGMPv3 *Membership Reports*.

IGMPv3 supports Source-Specific Multicast (SSM). SSM identifies session traffic by both source and group addresses.

The IGMPv3 implementation keeps records on the multicast hosts present in the network. If a host is already registered, when it receives a new *IS_INC*, *TO_INC*, *IS_EXC*, or *TO_EXC* report from same host, the switch makes the correct transition to new (port-host-group) registration based on the IGMPv3 RFC. The registrations of other hosts for the same group on the same port are not changed.

The G8264CS supports the following IGMPv3 filter modes:

- **INCLUDE** mode: The host requests membership to a multicast group and provides a list of IPv4 addresses from which it wants to receive traffic.
- **EXCLUDE** mode: The host requests membership to a multicast group and provides a list of IPv4 addresses from which it does not want to receive traffic. This indicates that the host wants to receive traffic only from sources that are not part of the Exclude list. To disable snooping on EXCLUDE mode reports, use the following command:

```
RS 8264CS(config)# no ip igmp snoop igmpv3 exclude
```

By default, the G8264CS snoops the first eight sources listed in the IGMPv3 Group Record. Use the following command to change the number of snooping sources:

```
RS 8264CS(config)# ip igmp snoop igmpv3 sources <1-64>
```

IGMPv3 Snooping is compatible with IGMPv1 and IGMPv2 Snooping. To disable snooping on version 1 and version 2 reports, use the following command:

```
RS 8264CS(config)# no ip igmp snoop igmpv3 v1v2
```

IGMP Snooping Configuration Guidelines

Consider the following guidelines when you configure IGMP Snooping:

- IGMP operation is independent of the routing method. You can use RIP, OSPF, or static routes for Layer 3 routing.
- When multicast traffic flood is disabled, the multicast traffic sent by the multicast server is discarded if no hosts or Mrouters are learned on the switch.
- The Mrouter periodically sends IGMP Queries.
- The switch learns the Mrouter on the port connected to the router when it sees Query messages. The switch then floods the IGMP queries on all other ports including a Trunk Group, if any.
- Multicast hosts send IGMP Reports as a reply to the IGMP Queries sent by the Mrouter.
- The switch can also learn an Mrouter when it receives a PIM hello packet from another device. However, an Mrouter learned from a PIM packet has a lower priority than an Mrouter learned from an IGMP Query. A switch overwrites an Mrouter learned from a PIM packet when it receives an IGMP Query on the same port.
- A host sends an IGMP Leave message to its multicast group. The expiration timer for this group is updated to 10 seconds. The Layer 3 switch sends IGMP Group-Specific Query to the host that had sent the Leave message. If the host does not respond with an IGMP Report during these 10 seconds, all the groups expire and the switch deletes the host from the IGMP groups table. The switch then proxies the IGMP Leave messages to the Mrouter.

IGMP Snooping Configuration Example

This section provides steps to configure IGMP Snooping on the G8264CS.

1. Configure port and VLAN membership on the switch.
2. Add VLANs to IGMP Snooping.

```
RS 8264CS(config)# ip igmp snoop vlan 1
```

3. Enable IGMP Snooping.

```
RS 8264CS(config)# ip igmp snoop enable
```

4. Enable IGMPv3 Snooping (optional).

```
RS 8264CS(config)# ip igmp snoop igmpv3 enable
```

5. Enable the IGMP feature.

```
RS 8264CS(config)# ip igmp enable
```

6. View dynamic IGMP information.

```
RS 8264CS# show ip igmp groups

Total entries: 5 Total IGMP groups: 3
Note: The <Total IGMP groups> number is computed as
      the number of unique (Group, Vlan) entries!
Note: Local groups (224.0.0.x) are not snooped/relayed and will not
      appear.

Source      Group      VLAN      Port      Version    Mode      Expires    Fwd
-----
10.1.1.1    232.1.1.1  2         4         V3         INC       4:16       Yes
10.1.1.5    232.1.1.1  2         4         V3         INC       4:16       Yes
*           232.1.1.1  2         4         V3         INC       -          No
10.10.10.43 235.0.0.1  9         1         V3         INC       2:26       Yes
*           236.0.0.1  9         1         V3         EXC       -          Yes

RS 8264CS# show ip igmp mrouter

Total entries: 3 Total number of dynamic mroouters: 2
Total number of installed static mroouters: 1

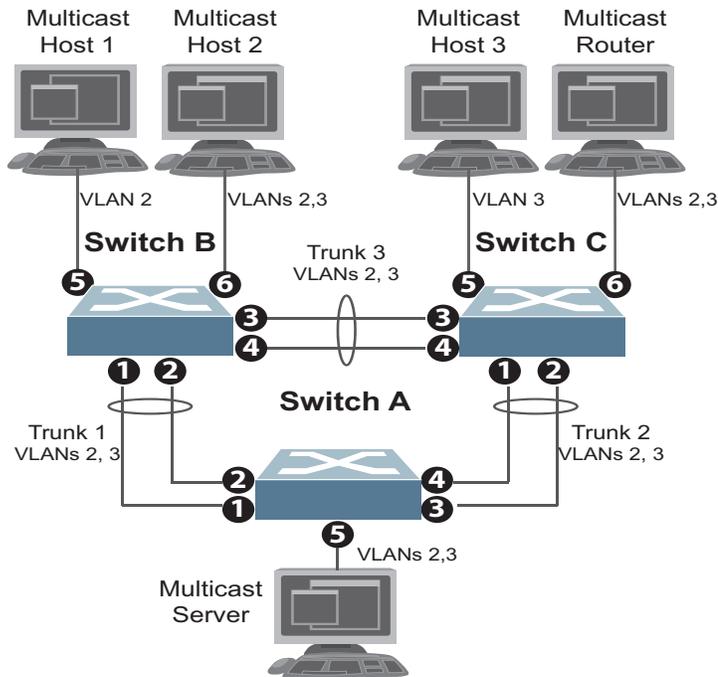

SrcIP      VLAN      Port      Version    Expires    MRT       QRV      QQIC
-----
10.1.1.1    2         21        V3         4:09      128      2        125
10.1.1.5    2         23        V2         4:09      125      -         -
*           9         24        V2         static    -         -         -
```

These commands display information about IGMP Groups and Mroouters learned by the switch.

Advanced Configuration Example: IGMP Snooping

Figure 34 shows an example topology. Switches B and C are configured with IGMP Snooping.

Figure 34. Topology

Devices in this topology are configured as follows:

- STG2 includes VLAN2; STG3 includes VLAN3.
- The multicast server sends IP multicast traffic for the following groups:
 - VLAN 2, 225.10.0.11 – 225.10.0.12, Source: 22.10.0.11
 - VLAN 2, 225.10.0.13 – 225.10.0.15, Source: 22.10.0.13
 - VLAN 3, 230.0.2.1 – 230.0.2.2, Source: 22.10.0.1
 - VLAN 3, 230.0.2.3 – 230.0.2.5, Source: 22.10.0.3
- The Mrouter sends IGMP Query packets in VLAN 2 and VLAN 3. The Mrouter's IP address is 10.10.10.10.
- The multicast hosts send the following IGMP Reports:
 - IGMPv2 Report, VLAN 2, Group: 225.10.0.11, Source: *
 - IGMPv2 Report, VLAN 3, Group: 230.0.2.1, Source: *
 - IGMPv3 IS_INCLUDE Report, VLAN 2, Group: 225.10.0.13, Source: 22.10.0.13
 - IGMPv3 IS_INCLUDE Report, VLAN 3, Group: 230.0.2.3, Source: 22.10.0.3

- The hosts receive multicast traffic as follows:
 - Host 1 receives multicast traffic for groups (*, 225.10.0.11), (22.10.0.13, 225.10.0.13)
 - Host 2 receives multicast traffic for groups (*, 225.10.0.11), (*, 230.0.2.1), (22.10.0.13, 225.10.0.13), (22.10.0.3, 230.0.2.3)
 - Host 3 receives multicast traffic for groups (*, 230.0.2.1), (22.10.0.3, 230.0.2.3)
- The Mrouter receives all the multicast traffic.

Prerequisites

Before you configure IGMP Snooping, ensure you have performed the following actions:

- Configured VLANs.
- Enabled IGMP.
- Added VLANs to IGMP Snooping.
- Configured a switch or Mrouter as the Querier.
- Identified the IGMP version(s) you want to enable.
- Disabled IGMP flooding.

Configuration

This section provides the configuration details of the switches shown in [Figure 34](#).

Switch A Configuration

1. Configure VLANs and tagging.

```
RS 8264CS(config)# interface port 1-5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 2,3
RS 8264CS(config-if)# switchport trunk allowed vlan remove 1
RS 8264CS(config-if)# exit
```

2. Configure an IP interface with IPv4 address, and assign a VLAN.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.10.1 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit
```

3. Assign a bridge priority lower than the default bridge priority to enable the switch to become the STP root in STG 2 and 3.

```
RS 8264CS(config)# spanning-tree stp 2 bridge priority 4096
RS 8264CS(config)# spanning-tree stp 3 bridge priority 4096
```

4. Configure LACP dynamic trunk groups (portchannels).

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# lacp key 100
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# lacp key 100
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 3
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 4
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# lacp mode active
```

Switch B Configuration

1. Configure VLANs and tagging.

```
RS 8264CS(config)# interface port 1-4,6
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 1-6
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 1-4,6
RS 8264CS(config-if)# switchport trunk allowed vlan add 3
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 1-5
RS 8264CS(config-if)# switchport trunk allowed vlan remove 1
RS 8264CS(config-if)# exit
```

2. Configure an IP interface with IPv4 address, and assign a VLAN.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.10.2 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit
```

3. Configure STP. Reset the ports to make the edge configuration operational.

```
RS 8264CS(config)# interface port 5,6
RS 8264CS(config-if)# spanning-tree portfast
RS 8264CS(config-if)# shutdown
RS 8264CS(config-if)# no shutdown
RS 8264CS(config-if)# exit
```

4. Configure an LACP dynamic trunk group (portchannel).

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 300
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

5. Configure a static trunk group (portchannel).

```
RS 8264CS(config)# portchannel 1 port 3,4 enable
```

6. Configure IGMP Snooping.

```
RS 8264CS(config)# ip igmp enable
RS 8264CS(config)# ip igmp snoop vlan 2,3
RS 8264CS(config)# ip igmp snoop source-ip 10.10.10.2
RS 8264CS(config)# ip igmp snoop igmpv3 enable
RS 8264CS(config)# ip igmp snoop igmpv3 sources 64
RS 8264CS(config)# ip igmp snoop enable

RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit

RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit
```

Switch C Configuration

1. Configure VLANs and tagging.

```
RS 8264CS(config)# interface port 1-4,6
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 1-4,6
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 1-6
RS 8264CS(config-if)# switchport trunk allowed vlan add 3
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface 1-6
RS 8264CS(config-if)# switchport trunk allowed vlan remove 1
RS 8264CS(config-if)# exit
```

2. Configure an IP interface with IPv4 address, and assign a VLAN.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.10.3 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit
```

3. Configure STP. Reset the ports to make the edge configuration operational.

```
RS 8264CS(config)# interface port 5,6
RS 8264CS(config-if)# spanning-tree portfast
RS 8264CS(config-if)# shutdown
RS 8264CS(config-if)# no shutdown
RS 8264CS(config-if)# exit
```

4. Configure an LACP dynamic trunk group (portchannel).

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 400
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

5. Configure a static trunk group (portchannel).

```
RS 8264CS(config)# portchannel 1 port 3,4 enable
```

6. Configure IGMP Snooping.

```
RS 8264CS(config)# ip igmp enable
RS 8264CS(config)# ip igmp snoop vlan 2,3
RS 8264CS(config)# ip igmp snoop source-ip 10.10.10.3
RS 8264CS(config)# ip igmp snoop igmpv3 enable
RS 8264CS(config)# ip igmp snoop igmpv3 sources 64
RS 8264CS(config)# ip igmp snoop enable

RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit

RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit
```

Troubleshooting

This section provides the steps to resolve common IGMP Snooping configuration issues. The topology described in [Figure 34](#) is used as an example.

Multicast traffic from non-member groups reaches the host or Mrouter

- Check if traffic is unregistered. For unregistered traffic, an IGMP entry is not displayed in the IGMP groups table.

```
RS 8264CS# show ip igmp groups
```

- Ensure IPMC flooding is disabled and CPU is enabled.

```
RS 8264CS(config)# vlan <vlan id>
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# cpu
```

- Check the egress port's VLAN membership. The ports to which the hosts and Mrouter are connected must be used only for VLAN 2 and VLAN 3.

```
RS 8264CS# show vlan
```

Note: To avoid such a scenario, disable IPMC flooding for all VLANs enabled on the switches (if this is an acceptable configuration).

- Check IGMP Reports on switches B and C for information about the IGMP groups.

```
RS 8264CS# show ip igmp groups
```

If the non-member IGMP groups are displayed in the table, close the application that may be sending the IGMP Reports for these groups.

Identify the traffic source by using a sniffer on the hosts and reading the source IP/MAC address. If the source IP/MAC address is unknown, check the port statistics to find the ingress port.

```
RS 8264CS# show interface port <port id> interface-counters
```

- Ensure no static multicast MACs, static multicast groups, or static Mrouters are configured.
- Ensure IGMP Relay and PIM are not configured.

Not all multicast traffic reaches the appropriate receivers.

- Ensure hosts are sending IGMP Reports for all the groups. Check the VLAN on which the groups are learned.

```
RS 8264CS# show ip igmp groups
```

If some of the groups are not displayed, ensure the multicast application is running on the host device and the generated IGMP Reports are correct.

- Ensure multicast traffic reaches the switch to which the host is connected. Close the application sending the IGMP Reports. Clear the IGMP groups by flapping (disabling, then re-enabling) the port.

Note: To clear all IGMP groups, use the following command:

```
RS 8264CS(config)# clear ip igmp groups
```

However, this will clear all the IGMP groups and will influence other hosts.

- Check if the multicast traffic reaches the switch.

```
RS 8264CS# show ip igmp ipmcgrp
```

If the multicast traffic group is not displayed in the table, check the link state, VLAN membership, and STP convergence.

- Ensure multicast server is sending all the multicast traffic.
- Ensure no static multicast MACs, static multicast groups, or static multicast routes are configured.

IGMP queries sent by the Mrouter do not reach the host.

- Ensure the Mrouter is learned on switches B and C.

```
RS 8264CS# show ip igmp mrouter
```

If it is not learned on switch B but is learned on switch C, check the link state of the trunk group, VLAN membership, and STP convergence.

If it is not learned on any switch, ensure the multicast application is running and is sending correct IGMP Query packets.

If it is learned on both switches, check the link state, VLAN membership, and STP port states for the ports connected to the hosts.

IGMP Reports/Leaves sent by the hosts do not reach the Mrouter

- Ensure IGMP Queries sent by the Mrouter reach the hosts.
- Ensure the Mrouter is learned on both switches. Note that the Mrouter may not be learned on switch B immediately after a trunk group failover/failback.

```
RS 8264CS# show ip igmp mrouter
```

- Ensure the host's multicast application is started and is sending correct IGMP Reports/Leaves.

```
RS 8264CS# show ip igmp groups
RS 8264CS# show ip igmp counters
```

A host receives multicast traffic from the incorrect VLAN

- Check port VLAN membership.
- Check IGMP Reports sent by the host.
- Check multicast data sent by the server.

The Mrouter is learned on the incorrect trunk group

- Check link state. Trunk group 1 might be down or in STP discarding state.
- Check STP convergence.
- Check port VLAN membership.

Hosts receive multicast traffic at a lower rate than normal

Note: This behavior is expected if IPMC flood is disabled and CPU is enabled. As soon as the IGMP/IPMC entries are installed on ASIC, the IPMC traffic recovers and is forwarded at line rate. This applies to unregistered IPMC traffic.

- Ensure a storm control is not configured on the trunks.

```
RS 8264CS(config)# interface port <port id>  
RS 8264CS(config-if)# no storm-control multicast
```

- Check link speeds and network congestion.

IGMP Relay

The G8264CS can act as an IGMP Relay (or IGMP Proxy) device that relays IGMP multicast messages and traffic between an Mrouter and end stations. IGMP Relay allows the G8264CS to participate in network multicasts with no configuration of the various multicast routing protocols, so you can deploy it in the network with minimal effort.

To an IGMP host connected to the G8264CS, IGMP Relay appears to be an IGMP Mrouter. IGMP Relay sends *Membership Queries* to hosts, which respond by sending an IGMP response message. A host can also send an unsolicited Join message to the IGMP Relay.

To an Mrouter, IGMP Relay appears as a host. The Mrouter sends IGMP host queries to IGMP Relay, and IGMP Relay responds by forwarding IGMP host reports and unsolicited Join messages from its attached hosts.

IGMP Relay also forwards multicast traffic between the Mrouter and end stations, similar to IGMP Snooping.

You can configure up to two Mrouters to use with IGMP Relay. One Mrouter acts as the primary Mrouter, and one is the backup Mrouter. The G8264CS uses health checks to select the primary Mrouter.

Configuration Guidelines

Consider the following guidelines when you configure IGMP Relay:

- IGMP Relay and IGMP Snooping are mutually exclusive—if you enable IGMP Relay, you must turn off IGMP Snooping/Querier.
- Add the upstream Mrouter VLAN to the IGMP Relay list, using the following command:

```
RS 8264CS(config)# ip igmp relay vlan <VLAN number>
```

- If IGMP hosts reside on different VLANs, you must:
 - Disable IGMP flooding.

```
RS 8264CS(config)# vlan <vlan id>  
RS 8264CS(config-vlan)# no flood
```

- Ensure CPU forwarding is enabled; Ensure that multicast data is forwarded across the VLANs.

```
RS 8264CS(config)# vlan <vlan id>  
RS 8264CS(config-vlan)# cpu
```

Configure IGMP Relay

Use the following procedure to configure IGMP Relay.

1. Configure IP interfaces with IPv4 addresses, and assign VLANs.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 10.10.1.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 10.10.2.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# vlan 3
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Turn IGMP on.

```
RS 8264CS(config)# ip igmp enable
```

3. Configure the upstream Mrouters with IPv4 addresses.

```
RS 8264CS(config)# ip igmp relay mrouter 1 address 100.0.1.2
RS 8264CS(config)# ip igmp relay mrouter 1 enable
RS 8264CS(config)# ip igmp relay mrouter 2 address 100.0.2.4
RS 8264CS(config)# ip igmp relay mrouter 2 enable
```

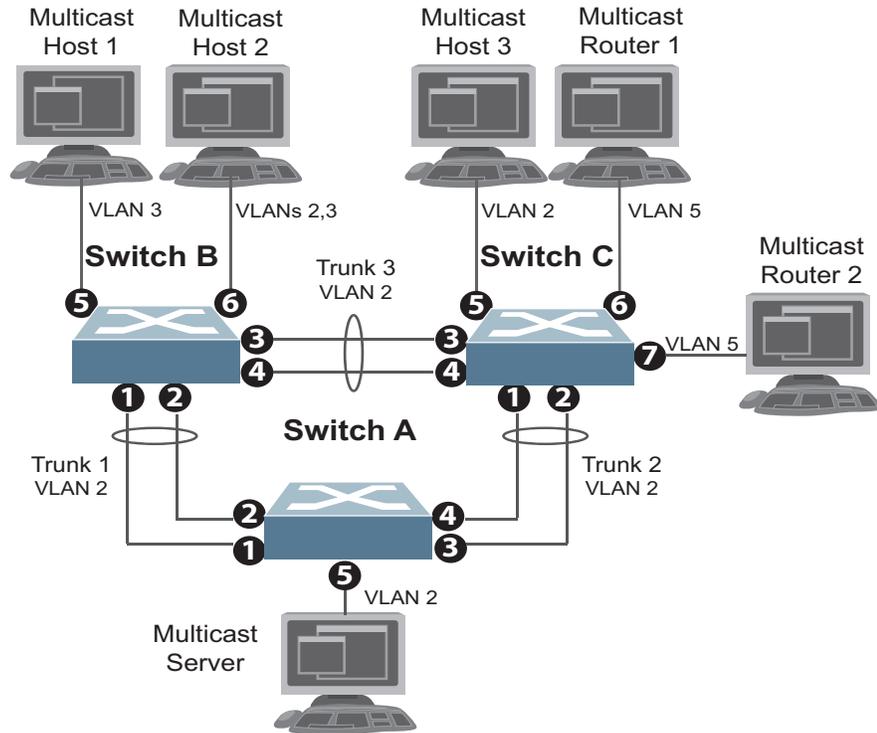

4. Enable IGMP Relay and add VLANs to the downstream network.

```
RS 8264CS(config)# ip igmp relay vlan 2
RS 8264CS(config)# ip igmp relay vlan 3
RS 8264CS(config)# ip igmp relay enable
```

Advanced Configuration Example: IGMP Relay

Figure 35 shows an example topology. Switches B and C are configured with IGMP Relay.

Figure 35. Topology

Devices in this topology are configured as follows:

- The IP address of Multicast Router 1 is 5.5.5.5
- The IP address of Multicast Router 2 is 5.5.5.6
- STG 2 includes VLAN2; STG 3 includes VLAN 3; STG 5 includes VLAN 5.
- The multicast server sends IP multicast traffic for the following groups:
 - VLAN 2, 225.10.0.11 – 225.10.0.15
- The multicast hosts send the following IGMP Reports:
 - Host 1: 225.10.0.11 – 225.10.0.12, VLAN 3
 - Host 2: 225.10.0.12 – 225.10.0.13, VLAN 2; 225.10.0.14 – 225.10.0.15, VLAN 3
 - Host 3: 225.10.0.13 – 225.10.0.14, VLAN 2
- The Mrouter receives all the multicast traffic.

Prerequisites

Before you configure IGMP Relay, ensure you have performed the following actions:

- Configured VLANs.

- Enabled IGMP.
- Disabled IGMP flooding.
- Disabled IGMP Snooping.

Configuration

This section provides the configuration details of the switches in [Figure 35](#).

Switch A Configuration

1. Configure a VLAN.

```
RS 8264CS(config)# interface port 1-5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit
```

2. Configure an IP interface with IPv4 address, and assign a VLAN..

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 2.2.2.10 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit
```

3. Assign a bridge priority lower than the default bridge priority to enable the switch to become the STP root in STG 2 and 3.

```
RS 8264CS(config)# spanning-tree stp 2 bridge priority 4096
```

4. Configure LACP dynamic trunk groups (portchannels).

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 100
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 3,4
RS 8264CS(config-if)# lacp key 200
RS 8264CS(config-if)# lacp mode active
```

Switch B Configuration

1. Configure VLANs and tagging.

```
RS 8264CS(config)# interface port 1-4,6
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 5,6
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 3
RS 8264CS(config-if)# exit
```

2. Configure IP interfaces with IPv4 addresses, and assign VLANs.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 2.2.2.20 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit

RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 3.3.3.20 enable
RS 8264CS(config-ip-if)# vlan 3
RS 8264CS(config-ip-if)# exit

RS 8264CS(config)# ip gateway 2 address 2.2.2.30 enable
```

3. Configure STP.

```
RS 8264CS(config)# interface port 5,6
RS 8264CS(config-if)# spanning-tree portfast
RS 8264CS(config-if)# shutdown
RS 8264CS(config-if)# no shutdown
RS 8264CS(config-if)# exit
```

4. Configure an LACP dynamic trunk group (portchannel).

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 300
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

5. Configure a static trunk group (portchannel).

```
RS 8264CS(config)# portchannel 1 port 3,4 enable
```

6. Configure IGMP Relay.

```
RS 8264CS(config)# ip igmp enable
RS 8264CS(config)# ip igmp relay vlan 2,3
RS 8264CS(config)# ip igmp relay mrouter 1 address 5.5.5.5 enable
RS 8264CS(config)# ip igmp relay mrouter 2 address 5.5.5.6 enable
RS 8264CS(config)# ip igmp relay enable

RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit

RS 8264CS(config)# vlan 3
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit
```

Switch C Configuration

1. Configure VLANs.

```
RS 8264CS(config)# interface port 1-5
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 2
RS 8264CS(config-if)# exit

RS 8264CS(config)# interface port 6,7
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 5
RS 8264CS(config-if)# exit
```

2. Configure IP interfaces with IPv4 addresses and assign VLANs.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 2.2.2.30 enable
RS 8264CS(config-ip-if)# vlan 2
RS 8264CS(config-ip-if)# exit

RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 5.5.5.30 enable
RS 8264CS(config-ip-if)# vlan 5
RS 8264CS(config-ip-if)# exit

RS 8264CS(config)# ip gateway 2 address 2.2.2.20 enable
```

3. Configure STP.

```
RS 8264CS(config)# interface port 5,6,7
RS 8264CS(config-if)# spanning-tree portfast
RS 8264CS(config-if)# shutdown
RS 8264CS(config-if)# no shutdown
RS 8264CS(config-if)# exit
```

4. Configure LACP dynamic trunk group (portchannel).

```
RS 8264CS(config)# interface port 1,2
RS 8264CS(config-if)# lacp key 400
RS 8264CS(config-if)# lacp mode active
RS 8264CS(config-if)# exit
```

5. Configure a static trunk group (portchannel).

```
RS 8264CS(config)# portchannel 1 port 3,4 enable
```

6. Enable IGMP.

```
RS 8264CS(config)# ip igmp enable
```

7. Configure IGMP Relay.

```
RS 8264CS(config)# ip igmp relay vlan 2,5
RS 8264CS(config)# ip igmp relay mrouter 1 address 5.5.5.5 enable
RS 8264CS(config)# ip igmp relay mrouter 2 address 5.5.5.6 enable
RS 8264CS(config)# ip igmp relay enable

RS 8264CS(config)# vlan 2
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit

RS 8264CS(config)# vlan 5
RS 8264CS(config-vlan)# no flood
RS 8264CS(config-vlan)# exit
```

Troubleshooting

This section provides the steps to resolve common IGMP Relay configuration issues. The topology described in [Figure 35](#) is used as an example.

Multicast traffic from non-member groups reaches the hosts or the Mrouter

- Ensure IPMC flood is disabled.

```
RS 8264CS(config)# vlan <vlan id>
RS 8264CS(config-vlan)# no flood
```

- Check the egress port's VLAN membership. The ports to which the hosts and Mrouter are connected must be used only for VLAN 2, VLAN 3, or VLAN 5.

```
RS 8264CS(config)# show vlan
```

Note: To avoid such a scenario, disable IPMC flooding for all VLANs enabled on the switches (if this is an acceptable configuration).

- Check IGMP Reports on switches B and C for information about IGMP groups.

```
RS 8264CS(config)# show ip igmp groups
```

If non-member IGMP groups are displayed in the table, close the application that may be sending the IGMP Reports for these groups.

Identify the traffic source by using a sniffer on the hosts and reading the source IP address/MAC address. If the source IP address/MAC address is unknown, check the port statistics to find the ingress port.

```
RS 8264CS(config)# show interface port <port id> interface-counters
```

- Ensure no static multicast MACs and static M routers are configured.

Not all multicast traffic reaches the appropriate receivers

- Ensure hosts are sending IGMP Reports for all the groups. Check the VLAN on which the groups are learned.

```
RS 8264CS(config)# show ip igmp groups
```

If some of the groups are not displayed, ensure the multicast application is running on the host device and the generated IGMP Reports are correct.

- Ensure the multicast traffic reaches the switch to which the host is connected. Close the application sending the IGMP Reports. Clear the IGMP groups by flapping (disabling, then re-enabling) the port.

Note: To clear all IGMP groups, use the following command:

```
RS 8264CS(config)# clear ip igmp groups
```

However, this will clear all the IGMP groups and will influence other hosts.

- Check if the multicast traffic reaches the switch.

```
RS 8264CS(config)# show ip igmp ipmgrp
```

If the multicast traffic group is not displayed in the table, check the link state, VLAN membership, and STP convergence.

- Ensure the multicast server is sending all the multicast traffic.
- Ensure no static multicast MACs or static multicast routes are configured.
- Ensure PIM is not enabled on the switches.

IGMP Reports/Leaves sent by the hosts do not reach the M router

- Ensure that the primary or secondary M router is reachable. If not, the IGMP Reports/Leaves are not forwarded. Note that the M router may not be reachable immediately after a trunk group failover/failback.

```
RS 8264CS(config)# show ip igmp groups
```

- Ensure the host's multicast application is started and is sending correct IGMP Reports/Leaves.

```
RS 8264CS(config)# show ip igmp groups
RS 8264CS(config)# show ip igmp counters
```

The Mrouter is reachable on the incorrect trunk group

- Check link state. Trunk group 1 may be down or in STP discarding state.
- Check STP convergence and port VLAN membership.
- Check IP connectivity between the switch and the configured Mrouter (primary or secondary).

Hosts receive multicast traffic at a lower rate than normal

- Ensure a multicast threshold is not configured on the trunk groups.

```
RS 8264CS(config)# interface port <port id>
RS 8264CS(config-if)# no storm-control multicast
```

- Check link speeds and network congestion.

Additional IGMP Features

The following topics are discussed in this section:

- “FastLeave” on page 379
- “IGMP Filtering” on page 379
- “Static Multicast Router” on page 380

FastLeave

In normal IGMP operation, when the switch receives an IGMPv2 Leave message, it sends a Group-Specific Query to determine if any other devices in the same group (and on the same port) are still interested in the specified multicast group traffic. The switch removes the affiliated port from that particular group, if the switch does not receive an IGMP Membership Report within the query-response-interval.

With FastLeave enabled on the VLAN, a port can be removed immediately from the port list of the group entry when the IGMP Leave message is received.

Note: Only IGMPv2 supports FastLeave. Enable FastLeave on ports that have only one host connected. If more than one host is connected to a port, you may lose some hosts unexpectedly.

Use the following command to enable FastLeave.

```
RS 8264CS(config)# ip igmp fastleave <VLAN number>
```

IGMP Filtering

With IGMP filtering, you can allow or deny certain IGMP groups to be learned on a port.

If access to a multicast group is denied, IGMP *Membership Reports* from the port are dropped, and the port is not allowed to receive IPv4 multicast traffic from that group. If access to the multicast group is allowed, Membership Reports from the port are forwarded for normal processing.

To configure IGMP filtering, you must globally enable IGMP filtering, define an IGMP filter, assign the filter to a port, and enable IGMP filtering on the port. To define an IGMP filter, you must configure a range of IPv4 multicast groups, choose whether the filter will allow or deny multicast traffic for groups within the range, and enable the filter.

Configuring the Range

Each IGMP filter allows you to set a start and end point that defines the range of IPv4 addresses upon which the filter takes action. Each IPv4 address in the range must be between 224.0.0.0 and 239.255.255.255.

Configuring the Action

Each IGMP filter can allow or deny IPv4 multicasts to the range of IPv4 addresses configured. If you configure the filter to deny IPv4 multicasts, then IGMP *Membership Reports* from multicast groups within the range are dropped. You can

configure a secondary filter to allow IPv4 multicasts to a small range of addresses within a larger range that a primary filter is configured to deny. The two filters work together to allow IPv4 multicasts to a small subset of addresses within the larger range of addresses.

Note: Lower-numbered filters take precedence over higher-number filters. For example, the action defined for IGMP filter 1 supersedes the action defined for IGMP filter 2.

Configure IGMP Filtering

1. Enable IGMP filtering on the switch.

```
RS 8264CS(config)# ip igmp filtering
```

2. Define an IGMP filter with IPv4 information.

```
RS 8264CS(config)# ip igmp profile 1 range 224.0.0.0 226.0.0.0
RS 8264CS(config)# ip igmp profile 1 action deny
RS 8264CS(config)# ip igmp profile 1 enable
```

3. Assign the IGMP filter to a port.

```
RS 8264CS(config)# interface port 3
RS 8264CS(config-if)# ip igmp profile 1
RS 8264CS(config-if)# ip igmp filtering
```

Static Multicast Router

A static Mrouter can be configured for a particular port on a particular VLAN. A static Mrouter does not have to be learned through IGMP Snooping. Any data port can accept a static Mrouter.

When you configure a static Mrouter on a VLAN, it replaces any dynamic Mrouters learned through IGMP Snooping.

Configure a Static Multicast Router

1. For each Mrouter, configure a port, VLAN, and IGMP version of the multicast router.

```
RS 8264CS(config)# ip igmp mrouter 5 1 2
```

2. Verify the configuration.

```
RS 8264CS(config)# show ip igmp mrouter
```

Chapter 265. Multicast Listener Discovery

Multicast Listener Discovery (MLD) is an IPv6 protocol that a host uses to request multicast data for a multicast group. An IPv6 router uses MLD to discover the presence of multicast listeners (nodes that want to receive multicast packets) on its directly attached links, and to discover specifically the multicast addresses that are of interest to those neighboring nodes.

MLD version 1 is derived from Internet Group Management Protocol version 2 (IGMPv2) and MLDv2 is derived from IGMPv3. MLD uses ICMPv6 (IP Protocol 58) message types. See RFC 2710 and RFC 3810 for details.

MLDv2 protocol, when compared to MLDv1, adds support for source filtering—the ability for a node to report interest in listening to packets only from specific source addresses, or from all but specific source addresses, sent to a particular multicast address. MLDv2 is interoperable with MLDv1. See RFC 3569 for details on Source-Specific Multicast (SSM).

The following topics are discussed in this chapter:

- [“MLD Terms” on page 382](#)
- [“How MLD Works” on page 383](#)
- [“MLD Capacity and Default Values” on page 386](#)
- [“Configuring MLD” on page 387](#)

MLD Terms

Following are the commonly used MLD terms:

- Multicast traffic: Flow of data from one source to multiple destinations.
- Group: A multicast stream to which a host can join.
- Multicast Router (Mrouter): A router configured to make routing decisions for multicast traffic. The router identifies the type of packet received (unicast or multicast) and forwards the packet to the intended destination.
- Querier: An Mrouter that sends periodic query messages. Only one Mrouter on the subnet can be elected as the Querier.
- Multicast Listener Query: Messages sent by the Querier. There are three types of queries:
 - General Query: Sent periodically to learn multicast address listeners from an attached link. G8264CS uses these queries to build and refresh the Multicast Address Listener state. General Queries are sent to the link-scope all-nodes multicast address (FF02::1), with a multicast address field of 0, and a maximum response delay of *query response interval*.
 - Multicast Address Specific Query: Sent to learn if a specific multicast address has any listeners on an attached link. The multicast address field is set to the IPv6 multicast address.
 - Multicast Address and Source Specific Query: Sent to learn if, for a specified multicast address, there are nodes still listening to a specific set of sources. Supported only in MLDv2.

Note: Multicast Address Specific Queries and Multicast Address and Source Specific Queries are sent only in response to State Change Reports, and never in response to Current State Reports.

- Multicast Listener Report: Sent by a host when it joins a multicast group, or in response to a Multicast Listener Query sent by the Querier. Hosts use these reports to indicate their current multicast listening state, or changes in the multicast listening state of their interfaces. These reports are of two types:
 - Current State Report: Contains the current Multicast Address Listening State of the host.
 - State Change Report: If the listening state of a host changes, the host immediately reports these changes through a State Change Report message. These reports contain either Filter Mode Change records and/or Source List Change records. State Change Reports are retransmitted several times to ensure all Mrouters receive it.
- Multicast Listener Done: Sent by a host when it wants to leave a multicast group. This message is sent to the link-scope all-routers IPv6 destination address of FF02::2. When an Mrouter receives a Multicast Listener Done message from the last member of the multicast address on a link, it stops forwarding traffic to this multicast address.

How MLD Works

The software uses the information obtained through MLD to maintain a list of multicast group memberships for each interface and forwards the multicast traffic only to interested listeners.

Without MLD, the switch forwards IPv6 multicast traffic through all ports, increasing network load. Following is an overview of operations when MLD is configured on the G8264CS:

- The switch acts as an Mrouter when MLDv1/v2 is configured and enabled on each of its directly attached links. If the switch has multiple interfaces connected to the same link, it operates the protocol on any one of the interfaces.
- If there are multiple Mrouters on the subnet, the Mrouter with the numerically lowest IPv6 address is elected as the Querier.
- The Querier sends general queries at short intervals to learn multicast address listener information from an attached link.
- Hosts respond to these queries by reporting their per-interface Multicast Address Listening state, through Current State Report messages sent to a specific multicast address that all MLD routers on the link listen to.
- If the listening state of a host changes, the host immediately reports these changes through a State Change Report message.
- The Querier sends a Multicast Address Specific Query to verify if hosts are listening to a specified multicast address or not. Similarly, if MLDv2 is configured, the Querier sends a Multicast Address and Source Specific Query to verify, for a specified multicast address, if hosts are listening to a specific set of sources, or not. MLDv2 listener report messages consists of Multicast Address Records:
 - INCLUDE: to receive packets from source specified in the MLDv2 message
 - EXCLUDE: to receive packets from all sources except the ones specified in the MLDv2 message
- A host can send a State Change Report to indicate its desire to stop listening to a particular multicast address (or source in MLDv2). The Querier then sends a multicast address specific query to verify if there are other listeners of the multicast address. If there aren't any, the Mrouter deletes the multicast address from its Multicast Address Listener state and stops sending multicast traffic. Similarly in MLDv2, the Mrouter sends a Multicast Address and Source Specific Query to verify if, for a specified multicast address, there are hosts still listening to a specific set of sources.

G8264CS supports MLD versions 1 and 2.

Note: MLDv2 operates in version 1 compatibility mode when, in a specific network, not all hosts are configured with MLDv2.

How Flooding Impacts MLD

When `flood` option is disabled, the unknown multicast traffic is discarded if no Mrouters are learned on the switch. You can set the flooding behavior by configuring the `flood` and `cpu` options. You can optimize the flooding to ensure that unknown IP multicast (IPMC) data packets are not dropped during the learning phase.

The flooding options include:

- `flood` : Enable hardware flooding in VLAN for the unregistered IPMC; This option is enabled by default.
- `cpu` : Enable sending unregistered IPMC to the Mrouter ports. However, during the learning period, there will be some packet loss. The `cpu` option is enabled by default. You must ensure that the `flood` and `opt flood` options are disabled.
- `opt flood` : Enable optimized flooding to allow sending the unregistered IPMC to the Mrouter ports without having any packet loss during the learning period; This option is disabled by default; When `opt flood` is enabled, the `flood` and `cpu` settings are ignored.

The flooding parameters must be configured per VLAN. Enter the following command to set the `flood` or `cpu` option:

```
RS 8264CS(config)# vlan <vlan number>  
RS 8264CS(config-vlan)# [no] flood  
RS 8264CS(config-vlan)# [no] cpu  
RS 8264CS(config-vlan)# [no] opt flood
```

MLD Querier

An Mrouter acts as a Querier and periodically (at short query intervals) sends query messages in the subnet. If there are multiple Mrouters in the subnet, only one can be the Querier. All Mrouters on the subnet listen to the messages sent by the multicast address listeners, and maintain the same multicast listening information state.

All MLDv2 queries are sent with the FE80::/64 link-local source address prefix.

Querier Election

Only one Mrouter can be the Querier per subnet. All other Mrouters will be non-Queriers. MLD versions 1 and 2 elect the Mrouter with the numerically lowest IPv6 address as the Querier.

If the switch is configured as an Mrouter on a subnet, it also acts as a Querier by default and sends multiple general queries. If the switch receives a general query from another Querier with a numerically lower IPv6 address, it sets the *other querier present timer* to the *other querier present timeout*, and changes its state to non-Querier. When the *other querier present timer* expires, it regains the Querier state and starts sending general queries.

Note: When MLD Querier is enabled on a VLAN, the switch performs the role of an MLD Querier only if it meets the MLD Querier election criteria.

Dynamic Mrouters

The switch learns Mrouters on the ingress VLANs of the MLD-enabled interface. All report or done messages are forwarded to these Mrouters. By default, the option of dynamically learning Mrouters is disabled. To enable it, use the following command:

```
RS 8264CS(config)# interface ip <interface number>  
RS 8264CS(config-ip-if)# ipv6 mld dmrtr enable
```

MLD Capacity and Default Values

Table 34 lists the maximum and minimum values of the G8264CS variables.

Table 34. *G8264CS Capacity Table*

Variable	Maximum Value
IPv6 Multicast Entries	256
IPv6 Interfaces for MLD	8

Note: IGMP and MLD share the IPMC table. When the IPMC table is full, you cannot allocate additional IGMP/MLD groups.

Table 35 lists the default settings for MLD features and variables.

Table 35. *MLD Timers and Default Values*

Field	Default Value
Robustness Variable (RV)	2
Query Interval (QI)	125 seconds
Query Response Interval (QRI)	10 seconds
Multicast Address Listeners Interval (MALI)	260 seconds [derived: $RV * QI + QRI$]
Other Querier Present Interval [OQPT]	255 seconds [derived: $RV * QI + \frac{1}{2} QRI$]
Start up Query Interval [SQI]	31.25 seconds [derived: $\frac{1}{4} * QI$]
Startup Query Count [SQC]	2 [derived: RV]
Last Listener Query Interval [LLQI]	1 second
Last Listener Query Count [LLQC]	2 [derived: RV]
Last Listener Query Time [LLQT]	2 seconds [derived: $LLQI * LLQT$]
Older Version Querier Present Timeout: [OVQPT]	260 seconds [derived: $RV * QI + QRI$]
Older Version Host Present Interval [OVHPT]	260 seconds [derived: $RV * QI + QRI$]

Configuring MLD

Following are the steps to enable MLD and configure the interface parameters:

1. Turn on MLD globally.

```
RS 8264CS(config)# ipv6 mld  
RS 8264CS(config-router-mld)# enable  
RS 8264CS(config-router-mld)# exit
```

2. Create an IPv6 interface.

```
RS 8264CS(config)# interface ip 2  
RS 8264CS(config-ip-if)# enable  
RS 8264CS(config-ip-if)# ipv6 address 2002:1:0:0:0:0:3  
RS 8264CS(config-ip-if)# ipv6 prefixlen 64
```

3. Enable MLD on the IPv6 interface.

```
RS 8264CS(config-ip-if)# ipv6 mld enable
```

4. Configure the MLD parameters on the interface: version, robustness, query response interval, MLD query interval, and last listener query interval.

```
RS 8264CS(config-ip-if)# ipv6 mld version <1-2>(MLD version)  
RS 8264CS(config-ip-if)# ipv6 mld robust <1-10>(Robustness)  
RS 8264CS(config-ip-if)# ipv6 mld qri <1-256>(In seconds)  
RS 8264CS(config-ip-if)# ipv6 mld qintrval <1-608>(In seconds)  
RS 8264CS(config-ip-if)# ipv6 mld llistnr <1-32>(In seconds)
```

Chapter 27. Border Gateway Protocol

Border Gateway Protocol (BGP) is an Internet protocol that enables routers on an IPv4 network to share and advertise routing information with each other about the segments of the IPv4 address space they can access within their network and with routers on external networks. BGP allows you to decide what is the “best” route for a packet to take from your network to a destination on another network rather than simply setting a default route from your border router(s) to your upstream provider(s). BGP is defined in RFC 1771.

RackSwitch G8264CSs can advertise their IP interfaces and IPv4 addresses using BGP and take BGP feeds from as many as 96 BGP router peers. This allows more resilience and flexibility in balancing traffic from the Internet.

Note: Lenovo Networking OS 8.2 does not support IPv6 for BGP.

The following topics are discussed in this section:

- [“Internal Routing Versus External Routing” on page 390](#)
- [“Forming BGP Peer Routers” on page 394](#)
- [“Loopback Interfaces” on page 396](#)
- [“What is a Route Map?” on page 396](#)
- [“Aggregating Routes” on page 400](#)
- [“Redistributing Routes” on page 400](#)
- [“BGP Attributes” on page 402](#)
- [“Selecting Route Paths in BGP” on page 404](#)
- [“BGP Failover Configuration” on page 405](#)
- [“Default Redistribution and Route Aggregation Example” on page 407](#)

Internal Routing Versus External Routing

To ensure effective processing of network traffic, every router on your network needs to know how to send a packet (directly or indirectly) to any other location/destination in your network. This is referred to as *internal routing* and can be done with static routes or using active, internal dynamic routing protocols, such as RIP, RIPv2, and OSPF.

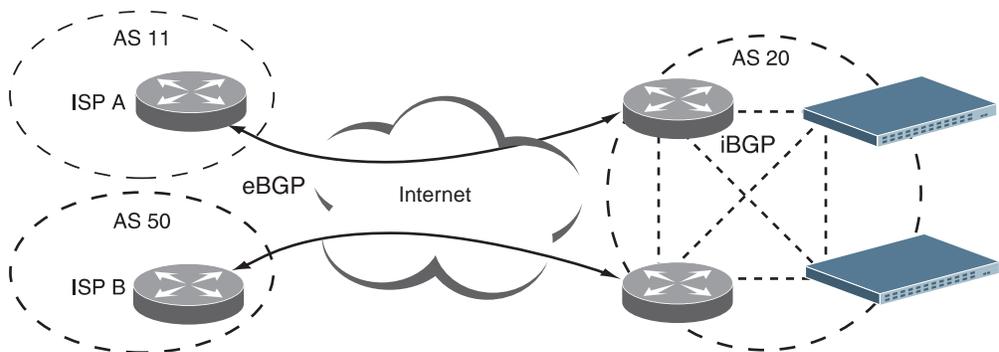

Static routes must have a higher degree of precedence than dynamic routing protocols. If the destination route is not in the route cache, the packets are forwarded to the default gateway which may be incorrect if a dynamic routing protocol is enabled.

It is also useful to tell routers outside your network (upstream providers or *peers*) about the routes you can access in your network. External networks (those outside your own) that are under the same administrative control are referred to as *autonomous systems* (AS). Sharing of routing information between autonomous systems is known as *external routing*.

External BGP (eBGP) is used to exchange routes between different autonomous systems whereas internal BGP (iBGP) is used to exchange routes within the same autonomous system. An iBGP is a type of internal routing protocol you can use to do active routing inside your network. It also carries AS path information, which is important when you are an ISP or doing BGP transit.

The iBGP peers have to maintain reciprocal sessions to every other iBGP router in the same AS (in a full-mesh manner) to propagate route information throughout the AS. If the iBGP session shown between the two routers in AS 20 was not present (as indicated in [Figure 36](#)), the top router would not learn the route to AS 50, and the bottom router would not learn the route to AS 11, even though the two AS 20 routers are connected via the RackSwitch G8264CS.

Figure 36. iBGP and eBGP

When there are many iBGP peers, having a full-mesh configuration results in large number of sessions between the iBGP peers. In such situations, configuring a route reflector eliminates the full-mesh configuration requirement, prevents route propagation loops, and provides better scalability to the peers. For details, see [“Route Reflector” on page 391](#).

Typically, an AS has one or more *border routers*—peer routers that exchange routes with other ASs—and an internal routing scheme that enables routers in that AS to reach every other router and destination within that AS. When you *advertise* routes to border routers on other autonomous systems, you are effectively committing to carry data to the IPv4 space represented in the route being advertised. For example, if you advertise 192.204.4.0/24, you are declaring that if another router sends you data destined for any address in 192.204.4.0/24, you know how to carry that data to its destination.

Route Reflector

The Lenovo N/OS implementation conforms to the BGP Route Reflection specification defined in RFC 4456.

As per RFC 1771 specification, a route received from an iBGP peer cannot be advertised to another iBGP peer. This makes it mandatory to have full-mesh iBGP sessions between all BGP routers within an AS. A route reflector—a BGP router—breaks this iBGP loop avoidance rule. It does not affect the eBGP behavior. A route reflector is a BGP speaker that advertises a route learnt from an iBGP peer to another iBGP peer. The advertised route is called the reflected route.

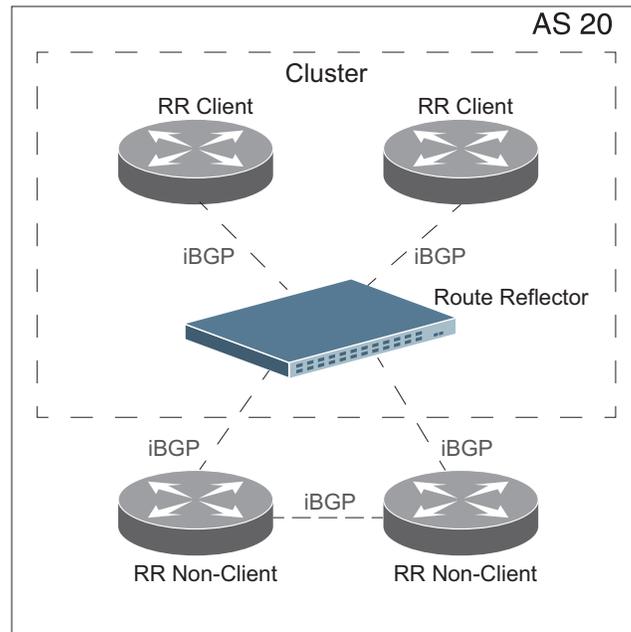

A route reflector has two groups of internal peers: clients and non-clients. A route reflector reflects between these groups and among the clients. The non-client peers must be fully meshed. The route reflector and its clients form a cluster.

When a route reflector receives a route from an iBGP peer, it selects the best path based on its path selection rule. It then does the following based on the type of peer it received the best path from:

- A route received from a non-client iBGP peer is reflected to all clients.
- A route received from an iBGP client peer is reflected to all iBGP clients and iBGP non-clients.

In [Figure 37](#), the G8264CS is configured as a route reflector. All clients and non-clients are in the same AS.

Figure 37. iBGP Route Reflector

The following attributes are used by the route reflector functionality:

- **ORIGINATOR ID:** BGP identifier (BGP router ID) of the route originator in the local AS. If the route does not have the ORIGINATOR ID attribute (it has not been reflected before), the router ID of the iBGP peer from which the route has been received is copied into the Originator ID attribute. This attribute is never modified by subsequent route reflectors. A router that identifies its own ID as the ORIGINATOR ID, it ignores the route.
- **CLUSTER LIST:** Sequence of the CLUSTER ID (i.e. router ID) values representing the reflection path that the route has passed. The value configured with the `RS 8264CS(config-router-bgp)# cluster-id <ID>` command (or the router ID of the route reflector if the cluster-id is not configured) is prepended to the Cluster list attribute. If a route reflector detects its own CLUSTER ID in the CLUSTER LIST, it ignores the route. Up to 10 CLUSTER IDs can be added to a CLUSTER LIST.

Route reflection functionality can be configured as follows:

1. Configure an AS.

```
RS 8264CS(config)# router bgp  
RS 8264CS(config-router-bgp)# as 22  
RS 8264CS(config-router-bgp)# enable
```

2. Configure a route reflector client.

```
RS 8264CS(config-router-bgp)# neighbor 2 remote-address 10.1.50.1  
RS 8264CS(config-router-bgp)# neighbor 2 remote-as 22  
RS 8264CS(config-router-bgp)# neighbor 2 route-reflector-client  
RS 8264CS(config-router-bgp)# no neighbor 2 shutdown
```

Note: When a client is configured on the G8264CS, the switch automatically gets configured as a route reflector.

3. Verify configuration.

```
RS 8264CS(config)# show ip bgp neighbor 2 information

BGP Peer 2 Information:
 2: 10.1.50.1          , version 0, TTL 255, TTL Security hops 0
Remote AS: 0, Local AS: 22, Link type: IBGP
Remote router ID: 0.0.0.0, Local router ID: 9.9.9.9
next-hop-self disabled
RR client enabled
BGP status: connect, Old status: connect
Total received packets: 0, Total sent packets: 0
Received updates: 0, Sent updates: 0
Keepalive: 0, Holdtime: 0, MinAdvTime: 60
LastErrorCode: unknown(0), LastErrorSubcode: unspecified(0)
Established state transitions: 0
```

Once configured as a route reflector, the switch, by default, passes routes between clients. If required, you can disable this by using the following command:

```
RS 8264CS(config-router-bgp)# no client-to-client reflection
```

You can view the route reflector BGP attributes attached to a BGP route using the following command:

```
RS 8264CS(config-router-bgp)# show ip bgp information 5.0.0.0
255.255.255.0
BGP routing table entry for 5.0.0.0/255.255.255.0
Paths: (1 available, best #1)
Multipath: eBGP
Local
 30.1.1.1 (metric 0) from 22.22.1.1(17.17.17.17)
Origin: IGP, localpref 0, valid, internal, best
Originator: 1.16.0.195
Cluster list: 17.17.17.17
```

Restrictions

Consider the following restrictions when configuring route reflection functionality:

- When a CLUSTER ID is changed, all iBGP sessions are restarted.
- When a route reflector client is enabled/disabled, the session is restarted.

Forming BGP Peer Routers

Two BGP routers become peers or neighbors once you establish a TCP connection between them. You can configure BGP peers statically or dynamically. While it may be desirable to configure static peers for security reasons, dynamic peers prove to be useful in cases where the remote address of the peer is unknown. For example in B-RAS applications, where subscriber interfaces are dynamically created and the address is assigned dynamically from a local pool or by using RADIUS.

For each new route, if a peer is interested in that route (for example, if a peer would like to receive your static routes and the new route is static), an update message is sent to that peer containing the new route. For each route removed from the route table, if the route has already been sent to a peer, an update message containing the route to withdraw is sent to that peer.

For each Internet host, you must be able to send a packet to that host, and that host has to have a path back to you. This means that whoever provides Internet connectivity to that host must have a path to you. Ultimately, this means that they must "hear a route" which covers the section of the IPv4 space you are using; otherwise, you will not have connectivity to the host in question.

Static Peers

You can configure BGP static peers by using the following commands:

```
RS 8264CS(config)# router bgp
RS 8264CS(config-router-bgp)# neighbor <1-96> remote-address <IP address>
RS 8264CS(config-router-bgp)# neighbor <1-96> remote-as <1-65535>
RS 8264CS(config-router-bgp)# no neighbor <1-96> shutdown
```

Static peers always take precedence over dynamic peers. Consider the following:

- If the remote address of an incoming BGP connection matches both a static peer address and an IP address from a dynamic group, the peer is configured statically and not dynamically.
- If a new static peer is enabled while a dynamic peer for the same remote address exists, BGP automatically removes the dynamic peer.
- If a new static peer is enabled when the maximum number of BGP peers were already configured, then BGP deletes the dynamic peer that was last created and adds the newly created static peer. A syslog will be generated for the peer that was deleted.

Dynamic Peers

To configure dynamic peers, you must define a range of IP addresses for a group. BGP waits to receive an open message initiated from BGP speakers within that range. Dynamic peers are automatically created when a peer group member accepts the incoming BGP connection. Dynamic peers are passive. When they are not in the established state, they accept inbound connections but do not initiate outbound connections.

You can configure up to 6 AS numbers per group. When the BGP speaker receives an open message from a dynamic peer, the AS number from the packet must match one of the remote AS numbers configured on the corresponding group.

When you delete a remote AS number, all dynamic peers established from that remote AS will be deleted.

You can define attributes for the dynamic peers only at the group level. You cannot configure attributes for any one dynamic peer. All static peer attributes, except the BGP passive mode, can also be configured for groups.

To set the maximum number of dynamic peers for a group that can simultaneously be in an established state, enter the following command:

```
RS 8264CS(config-router-bgp)# neighbor group <1-8> listen limit <1-96>
```

If you reset this limit to a lower number, and if the dynamic peers already established for the group are higher than this new limit, then BGP deletes the last created dynamic peer(s) until the new limit is reached.

Note: The maximum number of static and dynamic peers established simultaneously cannot exceed the maximum peers, i.e. 96, that the switch can support. If the maximum peers are established, no more dynamic peers will be enabled even if the maximum dynamic peers limit you had configured for the groups was not reached.

Given below are the basic commands for configuring dynamic peers:

```
RS 8264CS(config)# router bgp
RS 8264CS(config-router-bgp)# neighbor group <1-8> listen range
<IP address> <subnet mask> (Define
IP address range)
RS 8264CS(config-router-bgp)# neighbor group <1-8> remote-as <1-65535>
alternate-as <1-65535> (Enter up to 5
alternate AS numbers)
RS 8264CS(config-router-bgp)# no neighbor group <1-96> shutdown
```

Removing Dynamic Peers

You cannot remove dynamic peers manually. However, you can stop a dynamic peer using the following command:

```
RS 8264CS(config)# router bgp stop <neighbor number>
```

The stop command interrupts the BGP connection until the peer tries to re-establish the connection.

Also, when a dynamic peer state changes from established to idle, BGP removes the dynamic peer.

Loopback Interfaces

In many networks, multiple connections may exist between network devices. In such environments, it may be useful to employ a loopback interface for a common BGP router address, rather than peering the switch to each individual interface.

Note: To ensure that the loopback interface is reachable from peer devices, it must be advertised using an interior routing protocol (such as OSPF), or a static route must be configured on the peer.

To configure an existing loopback interface for BGP neighbor, use the following commands:

```
RS 8264CS(config)# router bgp
RS 8264CS(config-router-bgp)# neighbor <#> update-source loopback <1-5>
RS 8264CS(config-router-bgp)# exit
```

What is a Route Map?

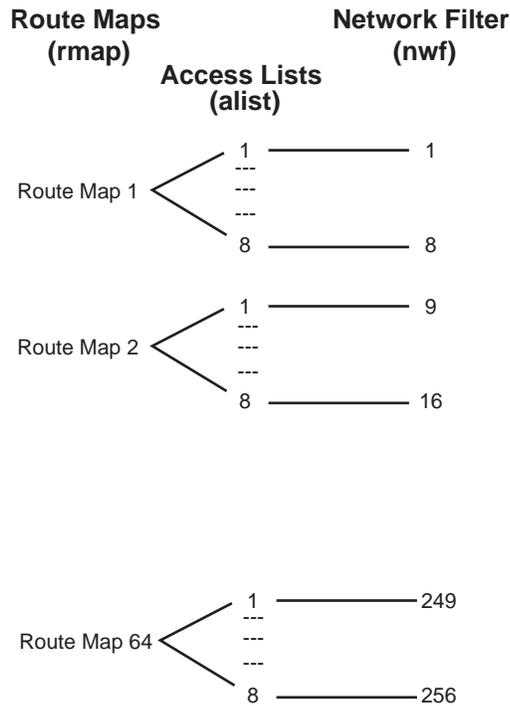

A route map is used to control and modify routing information. Route maps define conditions for redistributing routes from one routing protocol to another or controlling routing information when injecting it in and out of BGP. For example, a route map is used to set a preference value for a specific route from a peer router and another preference value for all other routes learned via the same peer router. For example, the following command is used to enter the Route Map mode for defining a route map:

```
RS 8264CS(config)# route-map <map number>(Select a route map)
RS 8264CS(config-route-map)# ? (List available commands)
```

A route map allows you to match attributes, such as metric, network address, and AS number. It also allows users to overwrite the local preference metric and to append the AS number in the AS route. See [“BGP Failover Configuration” on page 405](#).

Lenovo N/OS allows you to configure 64 route maps. Each route map can have up to eight access lists. Each access list consists of a network filter. A network filter defines an IPv4 address and subnet mask of the network that you want to include in the filter. [Figure 38](#) illustrates the relationship between route maps, access lists, and network filters.

Figure 38. Distributing Network Filters in Access Lists and Route Maps

Next Hop Peer IP Address

Next hop peer IP address can be configured only for route maps used in BGP. When a route map is applied on ingress, the next hop of learnt routes is replaced with peer IP address. When applied on egress, the next hop of the redistributed routes is replaced with the local IP address.

```
RS 8264CS(config)# route-map <map number>
RS 8264CS(config-router-map)# set ip next-hop <peer IP address>
```

Incoming and Outgoing Route Maps

You can have two types of route maps: incoming and outgoing. A BGP peer router can be configured to support up to eight route maps in the incoming route map list and outgoing route map list.

If a route map is not configured in the incoming route map list, the router imports all BGP updates. If a route map is configured in the incoming route map list, the router ignores all unmatched incoming updates. If you set the action to **deny**, you must add another route map to permit all unmatched updates.

Route maps in an outgoing route map list behave similar to route maps in an incoming route map list. If a route map is not configured in the outgoing route map list, all routes are advertised or permitted. If a route map in the outgoing route map list is set to **permit**, matched routes are advertised and unmatched routes are ignored.

Precedence

You can set a priority to a route map by specifying a precedence value with the following command (Route Map mode):

```
RS 8264CS(config)# route-map <map number>(Select a route map)
RS 8264CS(config-route-map)# precedence <1-255>(Specify a precedence)
RS 8264CS(config-route-map)# exit
```

The smaller the value the higher the precedence. If two route maps have the same precedence value, the smaller number has higher precedence.

Configuration Overview

To configure route maps, you need to do the following:

1. Define a network filter.

```
RS 8264CS(config)# ip match-address 1 <IPv4 address> <IPv4 subnet mask>
RS 8264CS(config)# ip match-address 1 enable
```

Enter a filter number from 1 to 256. Specify the IPv4 address and subnet mask of the network that you want to match. Enable the network filter. You can distribute up to 256 network filters among 64 route maps each containing eight access lists.

2. (Optional) Define the criteria for the access list and enable it.

Specify the access list and associate the network filter number configured in Step 1.

```
RS 8264CS(config)# route-map 1
RS 8264CS(config-route-map)# access-list 1 match-address 1
RS 8264CS(config-route-map)# access-list 1 metric <metric value>
RS 8264CS(config-route-map)# access-list 1 action deny
RS 8264CS(config-route-map)# access-list 1 enable
```

Steps 2 and 3 are optional, depending on the criteria that you want to match. In Step 2, the network filter number is used to match the subnets defined in the network filter. In Step 3, the autonomous system number is used to match the subnets. Or, you can use both (Step 2 and Step 3) criteria: access list (network filter) and access path (AS filter) to configure the route maps.

3. (Optional) Configure the AS filter attributes.

```
RS 8264CS(config-route-map)# as-path-list 1 as 1
RS 8264CS(config-route-map)# as-path-list 1 action deny
RS 8264CS(config-route-map)# as-path-list 1 enable
```

4. (Optional) Set up the BGP attributes.

If you want to overwrite the attributes that the peer router is sending, define the following BGP attributes:

- Specify up to three AS numbers that you want to prepend to a matched route and the local preference for the matched route.

- Specify the metric [Multi Exit Discriminator (MED)] for the matched route.

```
RS 8264CS(config-route-map)# as-path-preference <AS number> [<AS number>]
                                     [<AS number>]
RS 8264CS(config-route-map)# local-preference <local preference value>
RS 8264CS(config-route-map)# metric <metric value>
```

5. Enable the route map.

```
RS 8264CS(config-route-map)# enable
RS 8264CS(config-route-map)# exit
```

6. Turn BGP on.

```
RS 8264CS(config)# router bgp
RS 8264CS(config-router-bgp)# enable
```

7. Assign the route map to a peer router.

Select the peer router and then add the route map to the incoming route map list,

```
RS 8264CS(config-router-bgp)# neighbor 1 route-map in <1-64>
```

or to the outgoing route map list.

```
RS 8264CS(config-router-bgp)# neighbor 1 route-map out <1-64>
```

8. Exit Router BGP mode.

```
RS 8264CS(config-router-bgp)# exit
```

Aggregating Routes

Aggregation is the process of combining several different routes in such a way that a single route can be advertised, which minimizes the size of the routing table. You can configure aggregate routes in BGP either by redistributing an aggregate route into BGP or by creating an aggregate entry in the BGP routing table.

To define an aggregate route in the BGP routing table, use the following commands:

```
>> # router bgp
>> (config-router-bgp)# aggregate-address <1-16> <IPv4 address> <mask>
>> (config-router-bgp)# aggregate-address <1-16> enable
```

The origin code for the aggregated route is either IGP or INCOMPLETE.

An example of creating a BGP aggregate route is shown in [“Default Redistribution and Route Aggregation Example” on page 407](#).

Redistributing Routes

In addition to running multiple routing protocols simultaneously, N/OS software can redistribute information from one routing protocol to another. For example, you can instruct the switch to use BGP to re-advertise static routes. This applies to all of the IP-based routing protocols.

You can also conditionally control the redistribution of routes between routing domains by defining a method known as route maps between the two domains. For more information on route maps, see [“What is a Route Map?” on page 396](#). Redistributing routes is another way of providing policy control over whether to export OSPF routes, fixed routes, and static routes. For an example configuration, see [“Default Redistribution and Route Aggregation Example” on page 407](#).

Default routes can be configured using the following methods:

- Import
- Originate—The router sends a default route to peers if it does not have any default routes in its routing table.
- Redistribute—Default routes are either configured through the default gateway or learned via other protocols and redistributed to peer routers. If the default routes are from the default gateway, enable the static routes because default routes from the default gateway are static routes. Similarly, if the routes are learned from another routing protocol, make sure you enable that protocol for redistribution.
- None

The origin code for the redistributed routes is INCOMPLETE.

BGP Communities

BGP communities are attribute tags that allow controlled distribution of routing information based on an agreement between BGP peers. Communities are commonly used by transit service providers to enable peering customers to choose specific routing destinations for their outgoing routes. The transit service provider would typically publish a list of well-known or proprietary communities along with their descriptions, and take it upon itself to advertise incoming routes accordingly. For instance, an ISP may advertise that incoming routes tagged with community XY:01 will be advertised only to European peers while incoming routes tagged with community XY:02 will be advertised only to Asian peers.

The RackSwitch G8264CS can be configured to manage the community tags applied to the outgoing route updates. It does not, however, modify any routing decisions based on the community tags.

Up to 32 community tags can be applied to prefixes that pass a route-map. Valid values are between 0:0 and 65535:65535. Newly added communities will replace the existing communities. To set communities to prefixes that pass the route-map, use the following commands:

```
RS 8264CS(config)# route-map <map number>  
RS 8264CS(config-route-map)# set community {aa:nn [aa:nn]}
```

To remove all community tags from prefixes that pass the route-map, use the following command:

```
RS 8264CS(config-route-map)# set community none
```

To propagate prefixes that pass the route-map with their original community settings, use the following command:

```
RS 8264CS(config-route-map)# no set community
```

To enable or disable community tags forwarding for specific neighbors or neighbor groups, use the following commands:

```
RS 8264CS(config)# router bgp  
RS 8264CS(config-router-bgp)# neighbor 5 send-community  
RS 8264CS(config-router-bgp)# no neighbor 6 send-community  
RS 8264CS(config-router-bgp)# neighbor group 1 send-community
```

BGP Attributes

The following BGP attributes are discussed in this section: Local preference, metric (Multi-Exit Discriminator), and Next hop.

Local Preference Attribute

When there are multiple paths to the same destination, the local preference attribute indicates the preferred path. The path with the higher preference is preferred (the default value of the local preference attribute is 100). Unlike the weight attribute, which is only relevant to the local router, the local preference attribute is part of the routing update and is exchanged among routers in the same AS.

The local preference attribute can be set in one of two ways:

- The following commands use the BGP default local preference method, affecting the outbound direction only.

```
>> # router bgp
>> (config_router_bgp)# local-preference <0-4294967294>
>> (config_router_bgp)# exit
```

- The following commands use the route map local preference method, which affects both inbound and outbound directions.

```
>> # route-map 1
>> (config_route_map)# local-preference
>> (config_router_map)# exit
```

Metric (Multi-Exit Discriminator) Attribute

This attribute is a hint to external neighbors about the preferred path into an AS when there are multiple entry points. A lower metric value is preferred over a higher metric value. The default value of the metric attribute is 0.

Unlike local preference, the metric attribute is exchanged between ASs; however, a metric attribute that comes into an AS does not leave the AS.

When an update enters the AS with a certain metric value, that value is used for decision making within the AS. When BGP sends that update to another AS, the metric is reset to 0.

Unless otherwise specified, the router compares metric attributes for paths from external neighbors that are in the same AS.

Next Hop Attribute

BGP routing updates sent to a neighbor contain the next hop IP address used to reach a destination. In eBGP, the edge router, by default, sends its own IP address as the next hop address. However, this can sometimes cause routing path failures in Non-Broadcast Multiaccess Networks (NBMA) and when the edge router sends iBGP updates.

To avoid routing failures, you can manually configure the next hop IP address. In case of NBMA networks, you can configure the external BGP speaker to advertise its own IP address as the next hop. In case of iBGP updates, you can configure the edge iBGP router to send its IP address as the next hop.

Next hop can be configured on a BGP peer or a peer group. Use the following commands:

- Next Hop for a BGP Peer

```
RS 8264CS(config)# router bgp  
RS 8264CS(config-router-bgp)# neighbor <number> next-hop-self
```

- Next Hop for a BGP Peer Group:

```
RS 8264CS(config)# router bgp  
RS 8264CS(config-router-bgp)# neighbor group <number> next-hop-self
```

Selecting Route Paths in BGP

BGP selects only one path as the best path. It does not rely on metric attributes to determine the best path. When the same network is learned via more than one BGP peer, BGP uses its policy for selecting the best route to that network. The BGP implementation on the G8264CS uses the following criteria to select a path when the same route is received from multiple peers.

1. Local fixed and static routes are preferred over learned routes.
2. With iBGP peers, routes with higher local preference values are selected.
3. In the case of multiple routes of equal preference, the route with lower AS path weight is selected.

AS path weight = 128 x AS path length (number of autonomous systems traversed).

4. In the case of equal weight and routes learned from peers that reside in the same AS, the lower metric is selected.

Note: A route with a metric is preferred over a route without a metric.

5. In the case of equal cost, the eBGP route is preferred over iBGP.
6. The lower cost to the next hop of routes is selected.
7. If all routes have same route type (eBGP or iBGP), the route with the lower router ID is selected.
8. The first learned route is selected if the same router ID is present.

When the path is selected, BGP puts the selected path in its routing table and propagates the path to its neighbors.

Equal Cost Multi-Path

BGP can be configured to load balance the traffic over multiple paths if first six steps in path selection are identical and the next-hop of the route differs.

Multipath Relax

BGP multipath relax functionality allows load balancing across different autonomous system paths that have equal AS path length. This functionality can be enabled using the command:

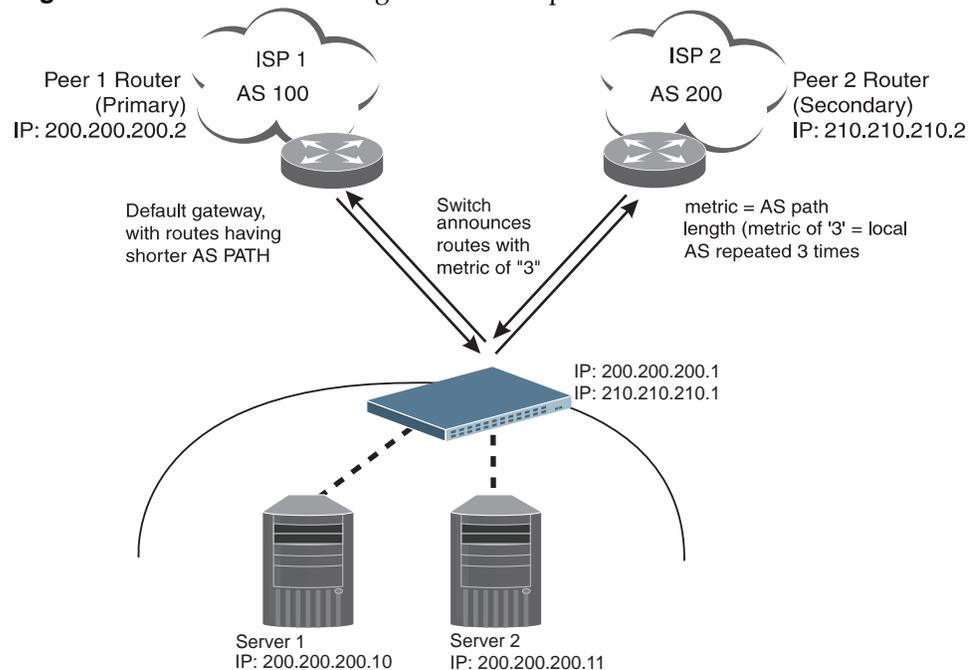

```
RS 8264CS(config-router-bgp)# bestpath as-path multipath-relax
```

BGP Failover Configuration

Use the following example to create redundant default gateways for a G8264CS at a Web Host/ISP site, eliminating the possibility, if one gateway goes down, that requests will be forwarded to an upstream router unknown to the switch.

As shown in [Figure 39](#), the switch is connected to ISP 1 and ISP 2. The customer negotiates with both ISPs to allow the switch to use their peer routers as default gateways. The ISP peer routers will then need to announce themselves as default gateways to the G8264CS.

Figure 39. BGP Failover Configuration Example

On the G8264CS, one peer router (the secondary one) is configured with a longer AS path than the other, so that the peer with the shorter AS path will be seen by the switch as the primary default gateway. ISP 2, the secondary peer, is configured with a metric of "3," thereby appearing to the switch to be three router *hops* away.

1. Define the VLANs.

For simplicity, both default gateways are configured in the same VLAN in this example. The gateways could be in the same VLAN or different VLANs.

```
RS 8264CS(config)# vlan 1
```

2. Define the IP interfaces with IPv4 addresses.

The switch will need an IP interface for each default gateway to which it will be connected. Each interface must be placed in the appropriate VLAN. These interfaces will be used as the primary and secondary default gateways for the switch.

```
>> # interface ip 1
>> (config-ip-if)# ip address 200.200.200.1
>> (config-ip-if)# ip netmask 255.255.255.0
>> (config-ip-if)# enable
>> (config-ip-if)# exit
>> # interface ip 2
>> (config-ip-if)# ip address 210.210.210.1
>> (config-ip-if)# ip netmask 255.255.255.0
>> (config-ip-if)# enable
>> (config-ip-if)# exit
```

3. Enable IP forwarding.

IP forwarding is turned on by default and is used for VLAN-to-VLAN (non-BGP) routing. Make sure IP forwarding is on if the default gateways are on different subnets or if the switch is connected to different subnets and those subnets need to communicate through the switch (which they almost always do).

```
>> # ip routing
```

Note: To help eliminate the possibility for a Denial of Service (DoS) attack, the forwarding of directed broadcasts is disabled by default.

4. Configure BGP peer router 1 and 2 with IPv4 addresses.

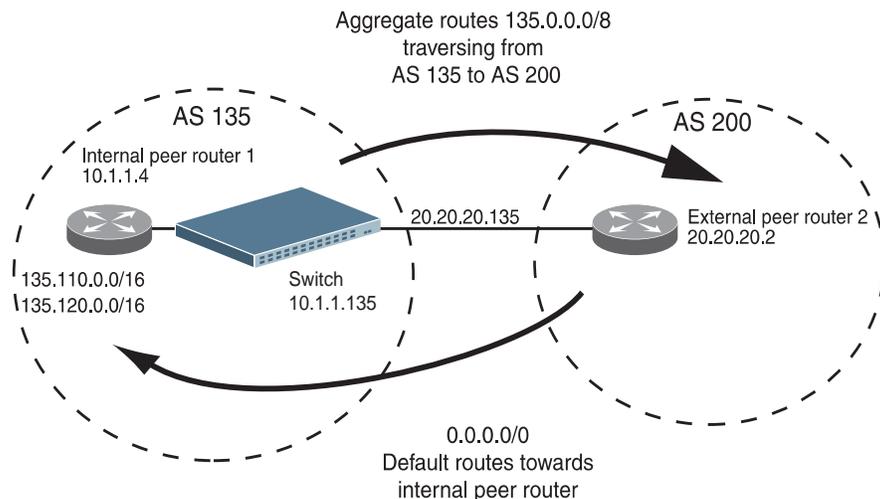

```
>> # router bgp
>> (config-router-bgp)# neighbor 1 remote-address 200.200.200.2
>> (config-router-bgp)# neighbor 1 remote-as 100
>> (config-router-bgp)# neighbor 2 remote-address 210.210.210.2
>> (config-router-bgp)# neighbor 2 remote-as 200
```

Default Redistribution and Route Aggregation Example

This example shows you how to configure the switch to redistribute information from one routing protocol to another and create an aggregate route entry in the BGP routing table to minimize the size of the routing table.

As illustrated in Figure 40, you have two peer routers: an internal and an external peer router. Configure the G8264CS to redistribute the default routes from AS 200 to AS 135. At the same time, configure for route aggregation to allow you to condense the number of routes traversing from AS 135 to AS 200.

Figure 40. Route Aggregation and Default Route Redistribution

1. Configure the IP interface.
2. Configure the AS number (AS 135) and router ID (10.1.1.135).

```
>> # router bgp
>> (config-router-bgp)# as 135
>> (config-router-bgp)# exit
>> # ip router-id 10.1.1.135
```

3. Configure internal peer router 1 and external peer router 2 with IPv4 addresses.

```
>> # router bgp
>> (config-router-bgp)# neighbor 1 remote-address 10.1.1.4
>> (config-router-bgp)# neighbor 1 remote-as 135
>> (config-router-bgp)# neighbor 2 remote-address 20.20.20.2
>> (config-router-bgp)# neighbor 2 remote-as 200
```

4. Configure redistribution for Peer 1.

```
>> (config-router-bgp)# neighbor 1 redistribute default-action
redistribute
>> (config-router-bgp)# neighbor 1 redistribute fixed
```

5. Configure aggregation policy control.

Configure the IPv4 routes that you want aggregated.

```
>> (config-router-bgp)# aggregate-address 1 135.0.0.0 255.0.0.0  
>> (config-router-bgp)# aggregate-address 1 enable
```

Chapter 28. OSPF

Lenovo Networking OS supports the Open Shortest Path First (OSPF) routing protocol. The Lenovo N/OS implementation conforms to the OSPF version 2 specifications detailed in Internet RFC 1583, and OSPF version 3 specifications in RFC 5340. The following sections discuss OSPF support for the RackSwitch G8264CS:

- [“OSPFv2 Overview” on page 410](#). This section provides information on OSPFv2 concepts, such as types of OSPF areas, types of routing devices, neighbors, adjacencies, link state database, authentication, and internal versus external routing.
- [“OSPFv2 Implementation in Lenovo N/OS” on page 415](#). This section describes how OSPFv2 is implemented in N/OS, such as configuration parameters, electing the designated router, summarizing routes, defining route maps and so forth.
- [“OSPFv2 Configuration Examples” on page 425](#). This section provides step-by-step instructions on configuring different OSPFv2 examples:
 - Creating a simple OSPF domain
 - Creating virtual links
 - Summarizing routes
- [“OSPFv3 Implementation in Lenovo N/OS” on page 434](#). This section describes differences and additional features found in OSPFv3.

OSPFv2 Overview

OSPF is designed for routing traffic within a single IP domain called an Autonomous System (AS). The AS can be divided into smaller logical units known as *areas*.

All routing devices maintain link information in their own Link State Database (LSDB). OSPF allows networks to be grouped together into an area. The topology of an area is hidden from the rest of the AS, thereby reducing routing traffic. Routing within an area is determined only by the area's own topology, thus protecting it from bad routing data. An area can be generalized as an IP subnetwork.

The following sections describe key OSPF concepts.

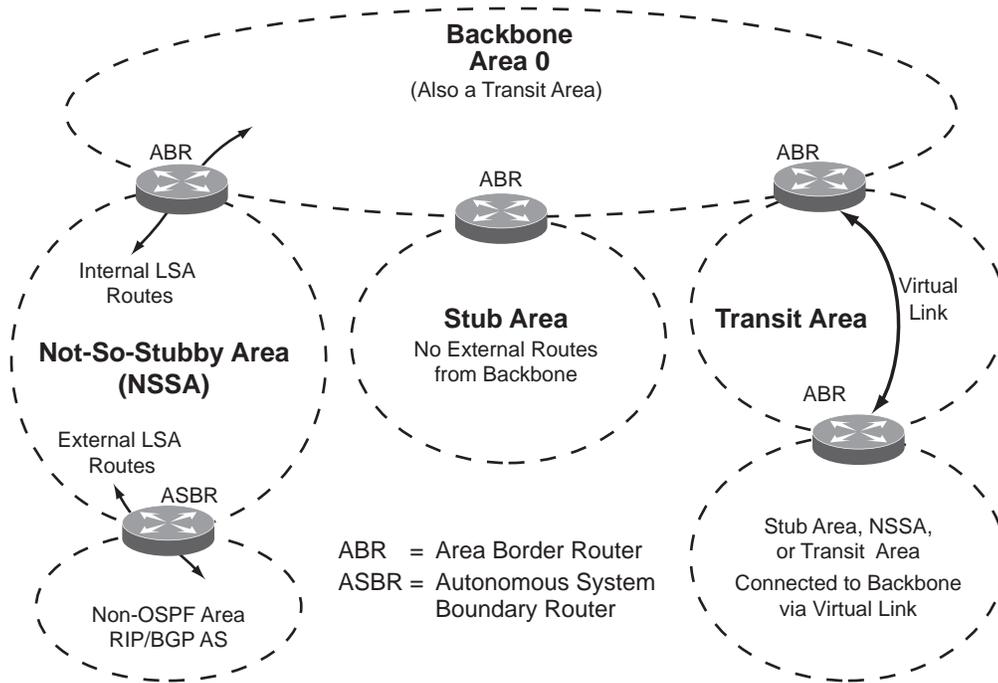

Types of OSPF Areas

An AS can be broken into logical units known as *areas*. In any AS with multiple areas, one area must be designated as area 0, known as the *backbone*. The backbone acts as the central OSPF area. All other areas in the AS must be connected to the backbone. Areas inject summary routing information into the backbone, which then distributes it to other areas as needed.

As shown in [Figure 41](#), OSPF defines the following types of areas:

- Stub Area—an area that is connected to only one other area. The stub area receives information from other areas, but external route information is not distributed into stub areas.
- Not-So-Stubby-Area (NSSA)—similar to a stub area with additional capabilities. Routes originating from within the NSSA can be propagated to adjacent transit and backbone areas. External routes from outside the AS can be advertised within the NSSA, but external routes coming from backbone area are not accepted.
- Transit Area—an area that also carries data traffic which neither originates nor terminates in the area itself.

Figure 41. OSPF Area Types

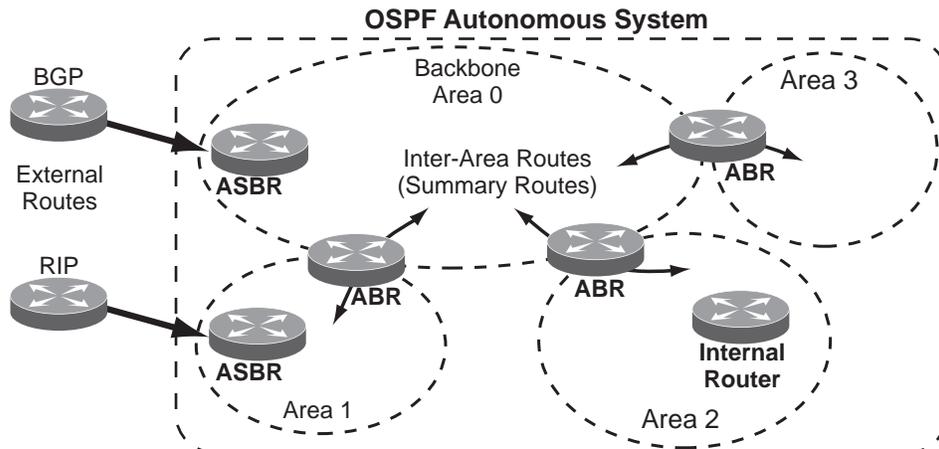

Types of OSPF Routing Devices

As shown in [Figure 42](#), OSPF uses the following types of routing devices:

- Internal Router (IR)—a router that has all of its interfaces within the same area. IRs maintain LSDBs identical to those of other routing devices within the local area.
- Area Border Router (ABR)—a router that has interfaces in multiple areas. ABRs maintain one LSDB for each connected area and disseminate routing information between areas.
- Autonomous System Boundary Router (ASBR)—a router that acts as a gateway between the OSPF domain and non-OSPF domains, such as RIP, BGP, and static routes.

Figure 42. OSPF Domain and an Autonomous System

Neighbors and Adjacencies

In areas with two or more routing devices, *neighbors* and *adjacencies* are formed.

Neighbors are routing devices that maintain information about each others' state. To establish neighbor relationships, routing devices periodically send hello packets on each of their interfaces. All routing devices that share a common network segment, appear in the same area, and have the same health parameters (hello and dead intervals) and authentication parameters respond to each other's hello packets and become neighbors. Neighbors continue to send periodic hello packets to advertise their health to neighbors. In turn, they listen to hello packets to determine the health of their neighbors and to establish contact with new neighbors.

The hello process is used for electing one of the neighbors as the network segment's Designated Router (DR) and one as the network segment's Backup Designated Router (BDR). The DR is adjacent to all other neighbors on that specific network segment and acts as the central contact for database exchanges. Each neighbor sends its database information to the DR, which relays the information to the other neighbors.

The BDR is adjacent to all other neighbors (including the DR). Each neighbor sends its database information to the BDR just as with the DR, but the BDR merely stores this data and does not distribute it. If the DR fails, the BDR will take over the task of distributing database information to the other neighbors.

The Link-State Database

OSPF is a link-state routing protocol. A *link* represents an interface (or routable path) from the routing device. By establishing an adjacency with other OSPF routers, each routing device in an OSPF area maintains an identical Link-State Database (LSDB) describing the network topology for its area.

Each routing device transmits a Link-State Advertisement (LSA) on each of its *active* interfaces. LSAs are entered into the LSDB of each routing device. OSPF uses *flooding* to distribute LSAs between routing devices. Interfaces may also be *passive*. Passive interfaces send LSAs to active interfaces, but do not receive LSAs, hello

packets, or any other OSPF protocol information from active interfaces. Passive interfaces behave as stub networks, allowing OSPF routing devices to be aware of devices that do otherwise participate in OSPF (either because they do not support it, or because the administrator chooses to restrict OSPF traffic exchange or transit).

When LSAs result in changes to the routing device's LSDB, the routing device forwards the changes to the adjacent neighbors (the DR and BDR) for distribution to the other neighbors.

OSPF routing updates occur only when changes occur, instead of periodically. For each new route, if a neighbor is interested in that route (for example, if configured to receive static routes and the new route is indeed static), an update message containing the new route is sent to the adjacency. For each route removed from the route table, if the route has already been sent to a neighbor, an update message containing the route to withdraw is sent.

The Shortest Path First Tree

The routing devices use a link-state algorithm (Dijkstra's algorithm) to calculate the shortest path to all known destinations, based on the cumulative *cost* required to reach the destination.

The cost of an individual interface in OSPF is an indication of the overhead required to send packets across it. The cost is inversely proportional to the bandwidth of the interface. A lower cost indicates a higher bandwidth.

Internal Versus External Routing

To ensure effective processing of network traffic, every routing device on your network needs to know how to send a packet (directly or indirectly) to any other location/destination in your network. This is referred to as *internal routing* and can be done with static routes or using active internal routing protocols, such as OSPF, RIP, or RIPv2.

It is also useful to tell routers outside your network (upstream providers or *peers*) about the routes you have access to in your network. Sharing of routing information between autonomous systems is known as *external routing*.

Typically, an AS will have one or more border routers (peer routers that exchange routes with other OSPF networks) as well as an internal routing system enabling every router in that AS to reach every other router and destination within that AS.

When a routing device *advertises* routes to boundary routers on other autonomous systems, it is effectively committing to carry data to the IP space represented in the route being advertised. For example, if the routing device advertises 192.204.4.0/24, it is declaring that if another router sends data destined for any address in the 192.204.4.0/24 range, it will carry that data to its destination.

OSPFv2 Implementation in Lenovo N/OS

N/OS supports a single instance of OSPF and up to 4K routes on the network. The following sections describe OSPF implementation in N/OS:

- [“Configurable Parameters” on page 415](#)
- [“Defining Areas” on page 416](#)
- [“Interface Cost” on page 418](#)
- [“Electing the Designated Router and Backup” on page 418](#)
- [“Summarizing Routes” on page 418](#)
- [“Default Routes” on page 419](#)
- [“Virtual Links” on page 420](#)
- [“Router ID” on page 420](#)
- [“Authentication” on page 421](#)

Configurable Parameters

In N/OS, OSPF parameters can be configured through the Command Line Interfaces (CLI/ISCLI), Browser-Based Interface (BBI), or through SNMP. For more information, see [“Switch Administration” on page 27](#).

The ISCLI supports the following parameters: interface output cost, interface priority, dead and hello intervals, retransmission interval, and interface transmit delay.

In addition to the preceding parameters, you can specify the following:

- Shortest Path First (SPF) interval—Time interval between successive calculations of the shortest path tree using the Dijkstra’s algorithm.
- Stub area metric—A stub area can be configured to send a numeric metric value such that all routes received via that stub area carry the configured metric to potentially influence routing decisions.
- Default routes—Default routes with weight metrics can be manually injected into transit areas. This helps establish a preferred route when multiple routing devices exist between two areas. It also helps route traffic to external networks.
- Passive—When enabled, the interface sends LSAs to upstream devices, but does not otherwise participate in OSPF protocol exchanges.
- Point-to-Point—For LANs that have only two OSPF routing agents (the G8264CS and one other device), this option allows the switch to significantly reduce the amount of routing information it must carry and manage.

Defining Areas

If you are configuring multiple areas in your OSPF domain, one of the areas must be designated as area 0, known as the *backbone*. The backbone is the central OSPF area and is usually physically connected to all other areas. The areas inject routing information into the backbone which, in turn, disseminates the information into other areas.

Since the backbone connects the areas in your network, it must be a contiguous area. If the backbone is partitioned (possibly as a result of joining separate OSPF networks), parts of the AS will be unreachable, and you will need to configure *virtual links* to reconnect the partitioned areas (see “[Virtual Links](#)” on page 420).

Up to six OSPF areas can be connected to the G8264CS with N/OS software. To configure an area, the OSPF number must be defined and then attached to a network interface on the switch. The full process is explained in the following sections.

An OSPF area is defined by assigning *two* pieces of information: an *area index* and an *area ID*. The commands to define and enable an OSPF area are as follows:

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area <area index> area-id <n.n.n.n>
RS 8264CS(config-router-ospf)# area <area index> enable
RS 8264CS(config-router-ospf)# exit
```

Note: The area option is an arbitrary index used only on the switch and does not represent the actual OSPF area number. The actual OSPF area number is defined in the area portion of the command as explained in the following sections.

Assigning the Area Index

The area <area index> option is actually just an arbitrary index (0–5) used only by the G8264CS. This index number does not necessarily represent the OSPF area number, though for configuration simplicity, it ought to where possible.

For example, both of the following sets of commands define OSPF area 0 (the backbone) and area 1 because that information is held in the area ID portion of the command. However, the first set of commands is easier to maintain because the arbitrary area indexes agree with the area IDs:

- Area index and area ID agree

```
area 0 area-id 0.0.0.0           (Use index 0 to set area 0 in ID octet format)
area 1 area-id 0.0.0.1           (Use index 1 to set area 1 in ID octet format)
```
- Area index set to an arbitrary value

```
area 1 area-id 0.0.0.0           (Use index 1 to set area 0 in ID octet format)
area 2 area-id 0.0.0.1           (Use index 2 to set area 1 in ID octet format)
```

Using the Area ID to Assign the OSPF Area Number

The OSPF area number is defined in the `areaid <IP address>` option. The octet format is used to be compatible with two different systems of notation used by other OSPF network vendors. There are two valid ways to designate an area ID:

- Single Number

Most common OSPF vendors express the area ID number as a single number. For example, the Cisco IOS-based router command “`network 1.1.1.0 0.0.0.255 area 1`” defines the area number simply as “area 1.”

- Multi-octet (*IP address*): Placing the area number in the last octet (0.0.0.*n*)

Some OSPF vendors express the area ID number in multi-octet format. For example, “area 0.0.0.2” represents OSPF area 2 and can be specified directly on the G8264CS as “area -id 0.0.0.2”.

On the G8264CS, you have to specify and configure the area ID (0.0.0.*n*) for each area you want to enable.

Attaching an Area to a Network

Once an OSPF area has been defined, it must be associated with a network. To attach the area to a network, you must assign the OSPF area index to an IP interface that participates in the area. The format for the command is as follows:

```
RS 8264CS(config)# interface ip <interface number>
RS 8264CS(config-ip-if)# ip ospf area <area index>
RS 8264CS(config-ip-if)# exit
```

For example, the following commands could be used to configure IP interface 14 to use 10.10.10.1 on the 10.10.10.0/24 network, to define OSPF area 1, and to attach the area to the network:

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# area 1 enable
RS 8264CS(config-router-ospf)# enable
RS 8264CS(config-router-ospf)# exit
RS 8264CS(config)# interface ip 14
RS 8264CS(config-ip-if)# ip address 10.10.10.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
```

Note: OSPFv2 supports IPv4 only. IPv6 is supported in OSPFv3 (see [“OSPFv3 Implementation in Lenovo N/OS” on page 434](#)).

Interface Cost

The OSPF link-state algorithm (Dijkstra's algorithm) places each routing device at the root of a tree and determines the cumulative *cost* required to reach each destination. Usually, the cost is inversely proportional to the bandwidth of the interface. Low cost indicates high bandwidth. You can manually enter the cost for the output route with the following command (Interface IP mode):

```
RS 8264CS(config-ip-if)# ip ospf cost <cost value (1-65535)>
```

Electing the Designated Router and Backup

In any area with more than two routing devices, a Designated Router (DR) is elected as the central contact for database exchanges among neighbors, and a Backup Designated Router (BDR) is elected in case the DR fails.

DR and BDR elections are made through the `hello` process. The election can be influenced by assigning a priority value to the OSPF interfaces on the G8264CS. The command is as follows:

```
RS 8264CS(config-ip-if)# ip ospf priority <priority value (0-255)>
```

A priority value of 255 is the highest, and 1 is the lowest. A priority value of 0 specifies that the interface cannot be used as a DR or BDR. In case of a tie, the routing device with the highest router ID wins. Interfaces configured as *passive* do not participate in the DR or BDR election process:

```
RS 8264CS(config-ip-if)# ip ospf passive-interface  
RS 8264CS(config-ip-if)# exit
```

Summarizing Routes

Route summarization condenses routing information. Without summarization, each routing device in an OSPF network would retain a route to every subnet in the network. With summarization, routing devices can reduce some sets of routes to a single advertisement, reducing both the load on the routing device and the perceived complexity of the network. The importance of route summarization increases with network size.

Summary routes can be defined for up to 16 IP address ranges using the following command:

```
RS 8264CS(config)# router ospf  
RS 8264CS(config-router-ospf)# area-range <range number> address <IP address>  
<mask>
```

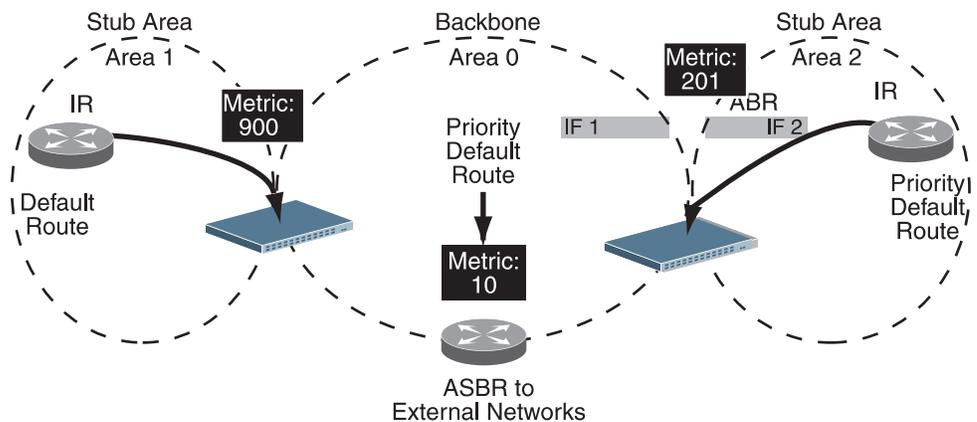

where *<range number>* is a number 1 to 16, *<IP address>* is the base IP address for the range, and *<mask>* is the IP address mask for the range. For a detailed configuration example, see [“Example 3: Summarizing Routes” on page 432](#).

Default Routes

When an OSPF routing device encounters traffic for a destination address it does not recognize, it forwards that traffic along the *default route*. Typically, the default route leads upstream toward the backbone until it reaches the intended area or an external router.

Each G8264CS acting as an ABR automatically inserts a default route into each attached area. In simple OSPF stub areas or NSSAs with only one ABR leading upstream (see Area 1 in [Figure 43](#)), any traffic for IP address destinations outside the area is forwarded to the switch's IP interface, and then into the connected transit area (usually the backbone). Since this is automatic, no further configuration is required for such areas.

Figure 43. Injecting Default Routes

If the switch is in a transit area and has a configured default gateway, it can inject a default route into rest of the OSPF domain. Use the following command to configure the switch to inject OSPF default routes (Router OSPF mode):

```
RS 8264CS(config-router-ospf)# default-information <metric value> <metric type (1 or 2)>
```

In this command, *<metric value>* sets the priority for choosing this switch for default route. The value *none* sets no default and 1 sets the highest priority for default route. Metric type determines the method for influencing routing decisions for external routes.

When the switch is configured to inject a default route, an AS-external LSA with link state ID 0.0.0.0 is propagated throughout the OSPF routing domain. This LSA is sent with the configured metric value and metric type.

The OSPF default route configuration can be removed with the command:

```
RS 8264CS(config-router-ospf)# no default-information
```

Virtual Links

Usually, all areas in an OSPF AS are physically connected to the backbone. In some cases where this is not possible, you can use a *virtual link*. Virtual links are created to connect one area to the backbone through another non-backbone area (see [Figure 41 on page 411](#)).

The area which contains a virtual link must be a transit area and have full routing information. Virtual links cannot be configured inside a stub area or NSSA. The area type must be defined as `transit` using the following command:

```
RS 8264CS(config-router-ospf)# area <area index> type transit
```

The virtual link must be configured on the routing devices at each endpoint of the virtual link, though they may traverse multiple routing devices. To configure a G8264CS as one endpoint of a virtual link, use the following command:

```
RS 8264CS(config-router-ospf)# area-virtual-link <link number>
neighbor-router <router ID>
```

where *<link number>* is a value between 1 and 3, *<area index>* is the OSPF area index of the transit area, and *<router ID>* is the IP address of the virtual neighbor, the routing device at the target endpoint. Another router ID is needed when configuring a virtual link in the other direction. To provide the G8264CS with a router ID, see the following section [Router ID](#).

For a detailed configuration example on Virtual Links, see [“Example 2: Virtual Links” on page 428](#).

Router ID

Routing devices in OSPF areas are identified by a router ID. The router ID is expressed in IP address format. The IP address of the router ID is not required to be included in any IP interface range or in any OSPF area, and may even use the G8264CS loopback interface.

The router ID can be configured in one of the following two ways:

- Dynamically—OSPF protocol configures the lowest IP interface IP address as the router ID (loopback interface has priority over the IP interface). This is the default.
- Statically—Use the following command to manually configure the router ID:

```
RS 8264CS(config-router-ospf)# ip router-id <IPv4 address>
```

If there is a loopback interface, its IP address is always preferred as the router ID, instead of an IP interface address. The `ip router-id` command is the preferred method to set the router ID and it is always used in preference to the other methods.

- To modify the router ID from static to dynamic, set the router ID to 0.0.0.0, save the configuration, and reboot the G8264CS.
- To view the router ID, use the following command:

```
RS 8264CS(config-router-ospf)# show ip ospf
```

Authentication

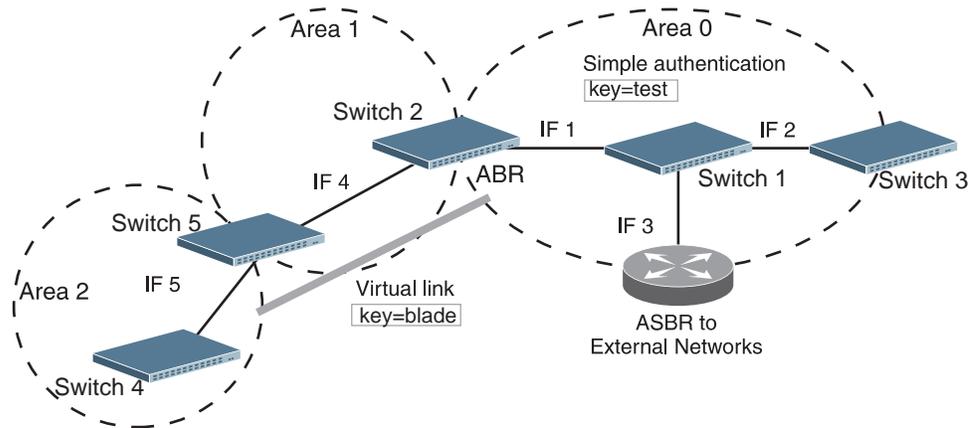

OSPF protocol exchanges can be authenticated so that only trusted routing devices can participate. This ensures less processing on routing devices that are not listening to OSPF packets.

OSPF allows packet authentication and uses IP multicast when sending and receiving packets. Routers participate in routing domains based on pre-defined passwords. N/OS supports simple password (type 1 plain text passwords) and MD5 cryptographic authentication. This type of authentication allows a password to be configured per area.

We strongly recommend that you implement MD5 cryptographic authentication as a best practice.

Figure 44 shows authentication configured for area 0 with the password test. Simple authentication is also configured for the virtual link between area 2 and area 0. Area 1 is not configured for OSPF authentication.

Figure 44. OSPF Authentication

Configuring Plain Text OSPF Passwords

To configure simple plain text OSPF passwords on the switches shown in [Figure 44](#) use the following commands:

1. Enable OSPF authentication for Area 0 on switches 1, 2, and 3.

```
RS 8264CS(config-router-ospf)# area 0 authentication-type password
RS 8264CS(config-router-ospf)# exit
```

2. Configure a simple text password up to eight characters for each OSPF IP interface in Area 0 on switches 1, 2, and 3.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip ospf key test
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip ospf key test
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip ospf key test
RS 8264CS(config-ip-if)# exit
```

3. Enable OSPF authentication for Area 2 on switch 4.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area 2 authentication-type password
```

4. Configure a simple text password up to eight characters for the virtual link between Area 2 and Area 0 on switches 2 and 4.

```
RS 8264CS(config-router-ospf)# area-virtual-link 1 key blade
```

Configuring MD5 Authentication

Use the following commands to configure MD5 authentication on the switches shown in [Figure 44](#):

1. Enable OSPF MD5 authentication for Area 0 on switches 1, 2, and 3.

```
RS 8264CS(config-router-ospf)# area 0 authentication-type md5
```

2. Configure MD5 key ID for Area 0 on switches 1, 2, and 3.

```
RS 8264CS(config-router-ospf)# message-digest-key 1 md5-key test
RS 8264CS(config-router-ospf)# exit
```

3. Assign MD5 key ID to OSPF interfaces on switches 1, 2, and 3.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip ospf message-digest-key 1
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip ospf message-digest-key 1
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip ospf message-digest-key 1
RS 8264CS(config-ip-if)# exit
```

4. Enable OSPF MD5 authentication for Area 2 on switch 4.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area 1 authentication-type md5
```

5. Configure MD5 key for the virtual link between Area 2 and Area 0 on switches 2 and 4.

```
RS 8264CS(config-router-ospf)# message-digest-key 2 md5-key test
```

6. Assign MD5 key ID to OSPF virtual link on switches 2 and 4.

```
RS 8264CS(config-router-ospf)# area-virtual-link 1 message-digest-key 2
RS 8264CS(config-router-ospf)# exit
```

Host Routes for Load Balancing

N/OS implementation of OSPF includes host routes. Host routes are used for advertising network device IP addresses to external networks, accomplishing the following goals:

- ABR Load Sharing

As a form of load balancing, host routes can be used for dividing OSPF traffic among multiple ABRs. To accomplish this, each switch provides identical services but advertises a host route for a different IP address to the external network. If each IP address serves a different and equal portion of the external world, incoming traffic from the upstream router must be split evenly among ABRs.

- ABR Failover

Complementing ABR load sharing, identical host routes can be configured on each ABR. These host routes can be given different costs so that a different ABR is selected as the preferred route for each server and the others are available as backups for failover purposes.

- Equal Cost Multipath (ECMP)

With equal cost multipath, a router potentially has several available next hops towards any given destination. ECMP allows separate routes to be calculated for each IP Type of Service. All paths of equal cost to a given destination are calculated, and the next hops for all equal-cost paths are inserted into the routing table.

Loopback Interfaces in OSPF

A loopback interface is an IP interface which has an IP address, but is not associated with any particular physical port. The loopback interface is thus always available to the general network, regardless of which specific ports are in operation. Because loopback interfaces are always available on the switch, loopback interfaces may present an advantage when used as the router ID.

If dynamic router ID selection is used (see [“Router ID” on page 420](#)) loopback interfaces can be used to force router ID selection. If a loopback interface is configured, its IP address is automatically selected as the router ID, even if other IP interfaces have lower IP addresses. If more than one loopback interface is configured, the lowest loopback interface IP address is selected.

Loopback interfaces can be advertised into the OSPF domain by specifying an OSPF host route with the loopback interface IP address.

To enable OSPF on an existing loopback interface:

```
RS 8264CS(config)# interface loopback <1-5>
RS 8264CS(config-ip-loopback)# ip ospf area <area ID> enable
RS 8264CS(config-ip-loopback)# exit
```

OSPF Features Not Supported in This Release

The following OSPF features are not supported in this release:

- Summarizing external routes
- Filtering OSPF routes
- Using OSPF to forward multicast routes
- Configuring OSPF on non-broadcast multi-access networks (such as frame relay, X.25, or ATM)

OSPFv2 Configuration Examples

A summary of the basic steps for configuring OSPF on the G8264CS is listed here. Detailed instructions for each of the steps is covered in the following sections:

1. Configure IP interfaces.

One IP interface is required for each desired network (range of IP addresses) being assigned to an OSPF area on the switch.

2. (Optional) Configure the router ID.

The router ID is required only when configuring virtual links on the switch.

3. Enable OSPF on the switch.

4. Define the OSPF areas.

5. Configure OSPF interface parameters.

IP interfaces are used for attaching networks to the various areas.

6. (Optional) Configure route summarization between OSPF areas.

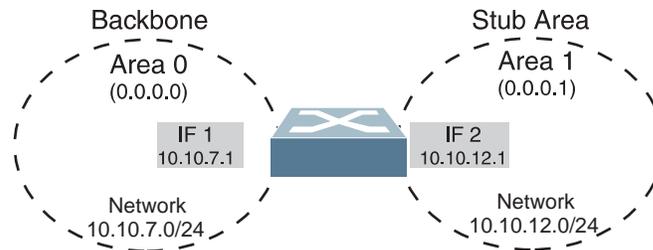

7. (Optional) Configure virtual links.

8. (Optional) Configure host routes.

Example 1: Simple OSPF Domain

In this example, two OSPF areas are defined—one area is the backbone and the other is a stub area. A stub area does not allow advertisements of external routes, thus reducing the size of the database. Instead, a default summary route of IP address 0.0.0.0 is automatically inserted into the stub area. Any traffic for IP address destinations outside the stub area will be forwarded to the stub area's IP interface, and then into the backbone.

Figure 45. A Simple OSPF Domain

Follow this procedure to configure OSPF support as shown in [Figure 45](#):

1. Configure IP interfaces on each network that will be attached to OSPF areas.

In this example, two IP interfaces are needed:

- Interface 1 for the backbone network on 10.10.7.0/24
- Interface 2 for the stub area network on 10.10.12.0/24

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.7.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 10.10.12.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

Note: OSPFv2 supports IPv4 only. IPv6 is supported in OSPFv3 (see [“OSPFv3 Implementation in Lenovo N/OS” on page 434](#)).

2. Enable OSPF.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# enable
```

3. Define the backbone.

The backbone is always configured as a transit area using areaid 0.0.0.0.

```
RS 8264CS(config-router-ospf)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf)# area 0 type transit
RS 8264CS(config-router-ospf)# area 0 enable
```

4. Define the stub area.

```
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1  
RS 8264CS(config-router-ospf)# area 1 type stub  
RS 8264CS(config-router-ospf)# area 1 enable  
RS 8264CS(config-router-ospf)# exit
```

5. Attach the network interface to the backbone.

```
RS 8264CS(config)# interface ip 1  
RS 8264CS(config-ip-if)# ip ospf area 0  
RS 8264CS(config-ip-if)# ip ospf enable  
RS 8264CS(config-ip-if)# exit
```

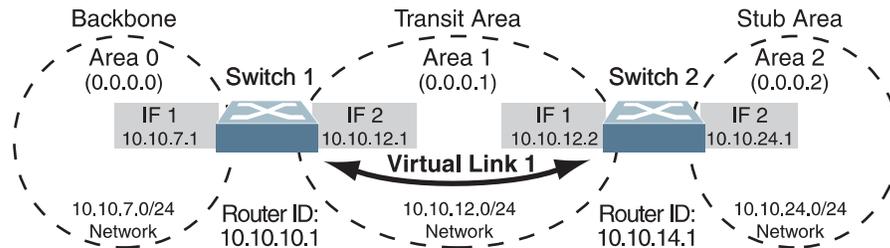

6. Attach the network interface to the stub area.

```
RS 8264CS(config)# interface ip 2  
RS 8264CS(config-ip-if)# ip ospf area 1  
RS 8264CS(config-ip-if)# ip ospf enable  
RS 8264CS(config-ip-if)# exit
```

Example 2: Virtual Links

In the example shown in [Figure 46](#), area 2 is not physically connected to the backbone as is usually required. Instead, area 2 will be connected to the backbone via a virtual link through area 1. The virtual link must be configured at each endpoint.

Figure 46. Configuring a Virtual Link

Note: OSPFv2 supports IPv4 only. IPv6 is supported in OSPFv3 (see [“OSPFv3 Implementation in Lenovo N/OS”](#) on page 434).

Configuring OSPF for a Virtual Link on Switch #1

1. Configure IP interfaces on each network that will be attached to the switch.

In this example, two IP interfaces are needed:

- Interface 1 for the backbone network on 10.10.7.0/24
- Interface 2 for the transit area network on 10.10.12.0/24

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.7.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 10.10.12.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Configure the router ID.

A router ID is required when configuring virtual links. Later, when configuring the other end of the virtual link on Switch 2, the router ID specified here will be used as the target virtual neighbor (nbr) address.

```
RS 8264CS(config)# ip router-id 10.10.10.1
```

3. Enable OSPF.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# enable
```

4. Define the backbone.

```
RS 8264CS(config-router-ospf)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf)# area 0 type transit
RS 8264CS(config-router-ospf)# area 0 enable
```

5. Define the transit area.

The area that contains the virtual link must be configured as a transit area.

```
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# area 1 type transit
RS 8264CS(config-router-ospf)# area 1 enable
RS 8264CS(config-router-ospf)# exit
```

6. Attach the network interface to the backbone.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip ospf area 0
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

7. Attach the network interface to the transit area.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

8. Configure the virtual link.

The `nbr` router ID configured in this step must be the same as the router ID that will be configured for Switch #2 in [Step 2 on page 430](#).

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area-virtual-link 1 area 1
RS 8264CS(config-router-ospf)# area-virtual-link 1 neighbor-router
10.10.14.1
RS 8264CS(config-router-ospf)# area-virtual-link 1 enable
```

Configuring OSPF for a Virtual Link on Switch #2

1. Configure IP interfaces on each network that will be attached to OSPF areas.

In this example, two IP interfaces are needed:

- Interface 1 for the transit area network on 10.10.12.0/24

- Interface 2 for the stub area network on 10.10.24.0/24

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.12.2
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 10.10.24.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Configure the router ID.

A router ID is required when configuring virtual links. This router ID must be the same one specified as the target virtual neighbor (nbr) on switch 1 in [Step 8 on page 429](#).

```
RS 8264CS(config)# ip router-id 10.10.14.1
```

3. Enable OSPF.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# enable
```

4. Define the backbone.

This version of N/OS requires that a backbone index be configured on the non-backbone end of the virtual link as follows:

```
RS 8264CS(config-router-ospf)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf)# area 0 enable
```

5. Define the transit area.

```
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# area 1 type transit
RS 8264CS(config-router-ospf)# area 1 enable
```

6. Define the stub area.

```
RS 8264CS(config-router-ospf)# area 2 area-id 0.0.0.2
RS 8264CS(config-router-ospf)# area 2 type stub
RS 8264CS(config-router-ospf)# area 2 enable
RS 8264CS(config-router-ospf)# exit
```

7. Attach the network interface to the transmit area.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

8. Attach the network interface to the stub area.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip ospf area 2
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

9. Configure the virtual link.

The `nbr` router ID configured in this step must be the same as the router ID that was configured for switch #1 in [Step 2 on page 428](#).

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area-virtual-link 1 area 1
RS 8264CS(config-router-ospf)# area-virtual-link 1 neighbor-router
10.10.10.1
RS 8264CS(config-router-ospf)# area-virtual-link 1 enable
```

Other Virtual Link Options

- You can use redundant paths by configuring multiple virtual links.
- Only the endpoints of the virtual link are configured. The virtual link path may traverse multiple routers in an area as long as there is a routable path between the endpoints.

Example 3: Summarizing Routes

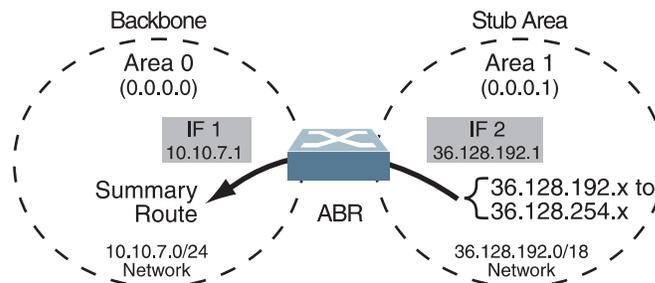

By default, ABRs advertise all the network addresses from one area into another area. Route summarization can be used for consolidating advertised addresses and reducing the perceived complexity of the network.

If network IP addresses in an area are assigned to a contiguous subnet range, you can configure the ABR to advertise a single summary route that includes all individual IP addresses within the area.

The following example shows one summary route from area 1 (stub area) injected into area 0 (the backbone). The summary route consists of all IP addresses from 36.128.192.0 through 36.128.254.255 except for the routes in the range 36.128.200.0 through 36.128.200.255.

Note: OSPFv2 supports IPv4 only. IPv6 is supported in OSPFv3 (see “[OSPFv3 Implementation in Lenovo N/OS](#)” on page 434).

Figure 47. Summarizing Routes

Note: You can specify a range of addresses to prevent advertising by using the `hide` option. In this example, routes in the range 36.128.200.0 through 36.128.200.255 are kept private.

Use the following procedure to configure OSPF support as shown in [Figure 47](#):

1. Configure IP interfaces for each network which will be attached to OSPF areas.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 10.10.7.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 36.128.192.1
RS 8264CS(config-ip-if)# ip netmask 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Enable OSPF.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# enable
```

3. Define the backbone.

```
RS 8264CS(config-router-ospf)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf)# area 0 type transit
RS 8264CS(config-router-ospf)# area 0 enable
```

4. Define the stub area.

```
RS 8264CS(config-router-ospf)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf)# area 1 type stub
RS 8264CS(config-router-ospf)# area 1 enable
RS 8264CS(config-router-ospf)# exit
```

5. Attach the network interface to the backbone.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip ospf area 0
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

6. Attach the network interface to the stub area.

```
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip ospf area 1
RS 8264CS(config-ip-if)# ip ospf enable
RS 8264CS(config-ip-if)# exit
```

7. Configure route summarization by specifying the starting address and mask of the range of addresses to be summarized.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area-range 1 address 36.128.192.0
255.255.192.0
RS 8264CS(config-router-ospf)# area-range 1 area 1
RS 8264CS(config-router-ospf)# area-range 1 enable
RS 8264CS(config-router-ospf)# exit
```

8. Use the hide command to prevent a range of addresses from advertising to the backbone.

```
RS 8264CS(config)# router ospf
RS 8264CS(config-router-ospf)# area-range 2 address 36.128.200.0
255.255.255.0
RS 8264CS(config-router-ospf)# area-range 2 area 1
RS 8264CS(config-router-ospf)# area-range 2 hide
RS 8264CS(config-router-ospf)# exit
```

Verifying OSPF Configuration

Use the following commands to verify the OSPF configuration on your switch:

- **show ip ospf**
- **show ip ospf neighbor**
- **show ip ospf database database-summary**
- **show ip ospf routes**

Refer to the *Lenovo Networking OS Command Reference* for information on the preceding commands.

OSPFv3 Implementation in Lenovo N/OS

OSPF version 3 is based on OSPF version 2, but has been modified to support IPv6 addressing. In most other ways, OSPFv3 is similar to OSPFv2: They both have the same packet types and interfaces, and both use the same mechanisms for neighbor discovery, adjacency formation, LSA flooding, aging, and so on. The administrator must be familiar with the OSPFv2 concepts covered in the preceding sections of this chapter before implementing the OSPFv3 differences as described in the following sections.

Although OSPFv2 and OSPFv3 are very similar, they represent independent features on the G8264CS. They are configured separately, and both can run in parallel on the switch with no relation to one another, serving different IPv6 and IPv4 traffic, respectively.

The Lenovo N/OS implementation conforms to the OSPF version 3 authentication/confidentiality specifications in RFC 4552.

OSPFv3 Differences from OSPFv2

Note: When OSPFv3 is enabled, the OSPF backbone area (0.0.0.0) is created by default and is always active.

OSPFv3 Requires IPv6 Interfaces

OSPFv3 is designed to support IPv6 addresses. This requires IPv6 interfaces to be configured on the switch and assigned to OSPF areas, in much the same way IPv4 interfaces are assigned to areas in OSPFv2. This is the primary configuration difference between OSPFv3 and OSPFv2.

See [“Internet Protocol Version 6” on page 323](#) for configuring IPv6 interfaces.

OSPFv3 Uses Independent Command Paths

Though OSPFv3 and OSPFv2 are very similar, they are configured independently. OSPFv3 command paths are located as follows:

- In the ISCLI

```
RS 8264CS(config)# ipv6 router ospf      (OSPFv3 router config mode)
RS 8264CS(config-router-ospf3)# ?

RS 8264CS(config)# interface ip <Interface number>(Configure OSPFv3)
RS 8264CS(config-ip-if)# ipv6 ospf ?    (OSPFv3 interface config)

RS 8264CS# show ipv6 ospf ?             (Show OSPFv3 information)
```

OSPFv3 Identifies Neighbors by Router ID

Where OSPFv2 uses a mix of IPv4 interface addresses and Router IDs to identify neighbors, depending on their type, OSPFv3 configuration consistently uses a Router ID to identify all neighbors.

Although Router IDs are written in dotted decimal notation, and may even be based on IPv4 addresses from an original OSPFv2 network configuration, it is important to realize that Router IDs are not IP addresses in OSPFv3, and can be assigned independently of IP address space. However, maintaining Router IDs consistent with any legacy OSPFv2 IPv4 addressing allows for easier implementation of both protocols.

Other Internal Improvements

OSPFv3 has numerous improvements that increase the protocol efficiency in addition to supporting IPv6 addressing. These improvements change some of the behaviors in the OSPFv3 network and may affect topology consideration, but have little direct impact on configuration. For example:

- Addressing fields have been removed from Router and Network LSAs.
- Flexible treatment of unknown LSA types to make integration of OSPFv3 easier.
- Interface network type can be specified using the command: `RS 8264CS(config-ip-if)# ipv6 ospf network {broadcast|non-broadcast|point-to-multipoint|point-to-point}`
- For an interface network type that is not broadcast or NBMA, link LSA suppression can be enabled so link LSA is not originated for the interface. Use the command: `RS 8264CS(config-ip-if)# ipv6 ospf linklsasuppress`

OSPFv3 Limitations

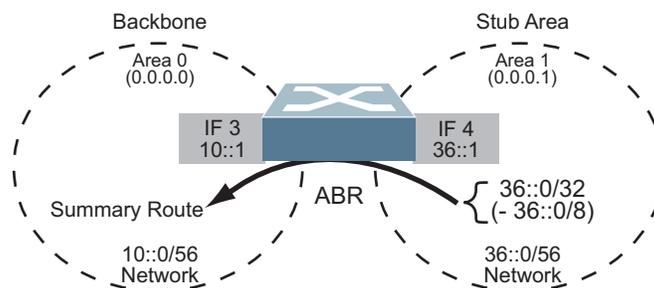

N/OS 8.2 does not currently support multiple interfaces of OSPFv3 on the same link.

OSPFv3 Configuration Example

The following example depicts the OSPFv3 equivalent configuration of [“Example 3: Summarizing Routes” on page 432](#) for OSPFv2.

In this example, one summary route from area 1 (stub area) is injected into area 0 (the backbone). The summary route consists of all IP addresses from the 36::0/32 portion of the 36::0/56 network, except for the routes in the 36::0/8 range.

Figure 48. Summarizing Routes

Note: You can specify a range of addresses to prevent advertising by using the `hide` option. In this example, routes in the 36::0/8 range are kept private.

Use the following procedure to configure OSPFv3 support as shown in [Figure 47](#):

1. Configure IPv6 interfaces for each link which will be attached to OSPFv3 areas.

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ipv6 address 10:0:0:0:0:0:1
RS 8264CS(config-ip-if)# ipv6 prefixlen 56
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 4
RS 8264CS(config-ip-if)# ip address 36:0:0:0:0:0:1
RS 8264CS(config-ip-if)# ipv6 prefixlen 56
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

This is equivalent to configuring the IP address and netmask for IPv4 interfaces.

2. Enable OSPFv3.

```
RS 8264CS(config)# ipv6 router ospf
RS 8264CS(config-router-ospf3)# enable
```

This is equivalent to the OSPFv2 `enable` option in the `router ospf` command path.

3. Define the backbone.

```
RS 8264CS(config-router-ospf3)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf3)# area 0 type transit
RS 8264CS(config-router-ospf3)# area 0 enable
```

This is identical to OSPFv2 configuration.

4. Define the stub area.

```
RS 8264CS(config-router-ospf3)# area 1 area-id 0.0.0.1
RS 8264CS(config-router-ospf3)# area 1 type stub
RS 8264CS(config-router-ospf3)# area 1 enable
RS 8264CS(config-router-ospf3)# exit
```

This is identical to OSPFv2 configuration.

5. Attach the network interface to the backbone.

```
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ipv6 ospf area 0
RS 8264CS(config-ip-if)# ipv6 ospf enable
RS 8264CS(config-ip-if)# exit
```

The `ipv6` command path is used instead of the OSPFv2 `ip` command path

6. Attach the network interface to the stub area.

```
RS 8264CS(config)# interface ip 4
RS 8264CS(config-ip-if)# ipv6 ospf area 1
RS 8264CS(config-ip-if)# ipv6 ospf enable
RS 8264CS(config-ip-if)# exit
```

The `ipv6` command path is used instead of the OSPFv2 `ip` command path

7. Configure route summarization by specifying the starting address and prefix length of the range of addresses to be summarized.

```
RS 8264CS(config)# ipv6 router ospf  
RS 8264CS(config-router-ospf3)# area-range 1 address 36:0:0:0:0:0:0 32  
RS 8264CS(config-router-ospf3)# area-range 1 area 0  
RS 8264CS(config-router-ospf3)# area-range 1 enable
```

This differs from OSPFv2 only in that the OSPFv3 command path is used, and the address and prefix are specified in IPv6 format.

8. Use the `hide` command to prevent a range of addresses from advertising to the backbone.

```
RS 8264CS(config-router-ospf)# area-range 2 address 36:0:0:0:0:0:0 8  
RS 8264CS(config-router-ospf)# area-range 2 area 0  
RS 8264CS(config-router-ospf)# area-range 2 hide  
RS 8264CS(config-router-ospf)# exit
```

This differs from OSPFv2 only in that the OSPFv3 command path is used, and the address and prefix are specified in IPv6 format.

Neighbor Configuration Example

When using NBMA or point to multipoint interfaces, you must manually configure neighbors. Following example includes the steps for neighbor configuration.

1. Configure IPv6 interface parameters:

```
RS 8264CS(config# interface ip 10
RS 8264CS(config-ip-if)# ipv6 address 10:0:0:0:0:0:12 64
RS 8264CS(config-ip-if)# vlan 10
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# ipv6 ospf area 0
RS 8264CS(config-ip-if)# ipv6 ospf retransmit-interval 5
RS 8264CS(config-ip-if)# ipv6 ospf transmit-delay 1
RS 8264CS(config-ip-if)# ipv6 ospf priority 1
RS 8264CS(config-ip-if)# ipv6 ospf hello-interval 10
RS 8264CS(config-ip-if)# ipv6 ospf dead-interval 40
RS 8264CS(config-ip-if)# ipv6 ospf network point-to-multipoint
RS 8264CS(config-ip-if)# ipv6 ospf poll-interval 120
RS 8264CS(config-ip-if)# ipv6 ospf enable
RS 8264CS(config-ip-if)# exit
```

2. Enable OSPFv3:

```
RS 8264CS(config# ipv6 router ospf
RS 8264CS(config-router-ospf3)# router-id 12.12.12.12
RS 8264CS(config-router-ospf3)# enable
```

3. Define the backbone.

```
RS 8264CS(config-router-ospf3)# area 0 area-id 0.0.0.0
RS 8264CS(config-router-ospf3)# area 0 stability-interval 40
RS 8264CS(config-router-ospf3)# area 0 default-metric 1
RS 8264CS(config-router-ospf3)# area 0 default-metric type 1
RS 8264CS(config-router-ospf3)# area 0 translation-role candidate
RS 8264CS(config-router-ospf3)# area 0 type transit
RS 8264CS(config-router-ospf3)# area 0 enable
```

4. Configure neighbor entry:

```
RS 8264CS(config-router-ospf3)# neighbor 1 address
fe80:0:0:0:dceb:ff:fe00:9
RS 8264CS(config-router-ospf3)# neighbor 1 interface 10
RS 8264CS(config-router-ospf3)# neighbor 1 priority 1
RS 8264CS(config-router-ospf3)# neighbor 1 enable
```

Chapter 29. Protocol Independent Multicast

Lenovo Networking OS supports Protocol Independent Multicast (PIM) in Sparse Mode (PIM-SM) and Dense Mode (PIM-DM).

Note: Lenovo N/OS 8.2 does not support IPv6 for PIM.

The following sections discuss PIM support for the RackSwitch G8264CS:

- [“PIM Overview” on page 440](#)
- [“Supported PIM Modes and Features” on page 441](#)
- [“Basic PIM Settings” on page 442](#)
- [“Additional Sparse Mode Settings” on page 445](#)
- [“Using PIM with Other Features” on page 448](#)
- [“PIM Configuration Examples” on page 449](#)

PIM Overview

PIM is designed for efficiently routing multicast traffic across one or more IPv4 domains. This has benefits for application such as IP television, collaboration, education, and software delivery, where a single source must deliver content (a multicast) to a group of receivers that span both wide-area and inter-domain networks.

Instead of sending a separate copy of content to each receiver, a multicast derives efficiency by sending only a single copy of content toward its intended receivers. This single copy only becomes duplicated when it reaches the target domain that includes multiple receivers, or when it reaches a necessary bifurcation point leading to different receiver domains.

PIM is used by multicast source stations, client receivers, and intermediary routers and switches, to build and maintain efficient multicast routing trees. PIM is protocol independent; It collects routing information using the existing unicast routing functions underlying the IPv4 network, but does not rely on any particular unicast protocol. For PIM to function, a Layer 3 routing protocol (such as BGP, OSPF, RIP, or static routes) must first be configured on the switch.

PIM-SM is a reverse-path routing mechanism. Client receiver stations advertise their willingness to join a multicast group. The local routing and switching devices collect multicast routing information and forward the request toward the station that will provide the multicast content. When the join requests reach the sending station, the multicast data is sent toward the receivers, flowing in the opposite direction of the original join requests.

Some routing and switching devices perform special PIM-SM functions. Within each receiver domain, one router is elected as the Designated Router (DR) for handling multicasts for the domain. DRs forward information to a similar device, the Rendezvous Point (RP), which holds the root tree for the particular multicast group.

Receiver join requests as well as sender multicast content initially converge at the RP, which generates and distributes multicast routing data for the DRs along the delivery path. As the multicast content flows, DRs use the routing tree information obtained from the RP to optimize the paths both to and from send and receive stations, bypassing the RP for the remainder of content transactions if a more efficient route is available.

DRs continue to share routing information with the RP, modifying the multicast routing tree when new receivers join, or pruning the tree when all the receivers in any particular domain are no longer part of the multicast group.

Supported PIM Modes and Features

For each interface attached to a PIM network component, PIM can be configured to operate either in PIM Sparse Mode (PIM-SM) or PIM Dense Mode (PIM-DM).

- PIM-SM is used in networks where multicast senders and receivers comprise a relatively small (sparse) portion of the overall network. PIM-SM uses a more complex process than PIM-DM for collecting and optimizing multicast routes, but minimizes impact on other IP services and is more commonly used.
- PIM-DM is used where multicast devices are a relatively large (dense) portion of the network, with very frequent (or constant) multicast traffic. PIM-DM requires less configuration on the switch than PIM-SM, but uses broadcasts that can consume more bandwidth in establishing and optimizing routes.

The following PIM modes and features are *not* currently supported in N/OS 8.2:

- Hybrid Sparse-Dense Mode (PIM-SM/DM). Sparse Mode and Dense Mode may be configured on separate IP interfaces on the switch, but are not currently supported simultaneously on the same IP interface.
- PIM Source-Specific Multicast (PIM-SSM)
- Anycast RP
- PIM RP filters
- Only configuration via the switch CLI is supported. PIM configuration is currently not available using the BBI or via SNMP.

Basic PIM Settings

To use PIM the following is required:

- The PIM feature must be enabled globally on the switch.
- PIM network components and PIM modes must be defined.
- IP interfaces must be configured for each PIM component.
- PIM neighbor filters may be defined (optional).
- If PIM-SM is used, define additional parameters:
 - Rendezvous Point
 - Designated Router preferences (optional)
 - Bootstrap Router preferences (optional)

Each of these tasks is covered in the following sections.

Note: In N/OS 8.2, PIM can be configured through the switch CLI only. PIM configuration and information are not available using the BBI or via SNMP.

Globally Enabling or Disabling the PIM Feature

By default, PIM is disabled on the switch. PIM can be globally enabled or disabled using the following commands:

```
RS 8264CS(config)# [no] ip pim enable
```

Defining a PIM Network Component

The G8264CS can be attached to a maximum of two independent PIM network components. Each component represents a different PIM network, and can be defined for either PIM-SM or PIM-DM operation. Basic PIM component configuration is performed using the following commands:

```
RS 8264CS(config)# ip pim component <1-2>  
RS 8264CS(config-ip-pim-comp)# mode {sparse|dense}  
RS 8264CS(config-ip-pim-comp)# exit
```

The sparse option will place the component in Sparse Mode (PIM-SM). The dense option will place the component in Dense Mode (PIM-DM). By default, PIM component 1 is configured for Sparse Mode. PIM component 2 is unconfigured by default.

Note: A component using PIM-SM must also be configured with a dynamic or static Rendezvous Point (see [“Specifying the Rendezvous Point” on page 445](#)).

Defining an IP Interface for PIM Use

Each network attached to an IP interface on the switch may be assigned one of the available PIM components. The same PIM component can be assigned to multiple IP interfaces. The interfaces may belong to the same VLAN, and they may also belong to different VLANs as long as their member IP addresses do not overlap.

To define an IP interface for use with PIM, first configured the interface with an IPv4 address and VLAN as follows:

```
RS 8264CS(config)# interface ip <Interface number>
RS 8264CS(config-ip-if)# ip address <IPv4 address> <IPv4 mask>
RS 8264CS(config-ip-if)# vlan <VLAN number>
RS 8264CS(config-ip-if)# enable
```

Note: The PIM feature currently supports only one VLAN for each IP interface. Configurations where different interfaces on different VLANs share IP addresses are not supported.

Next, PIM must be enabled on the interface, and the PIM network component ID must be specified:

```
RS 8264CS(config-ip-if)# ip pim enable
RS 8264CS(config-ip-if)# ip pim component-id <1-2>
RS 8264CS(config-ip-if)# exit
```

By default, PIM component 1 is automatically assigned when PIM is enabled on the IP interface.

Note: While PIM is enabled on the interface, the interface VLAN cannot be changed. To change the VLAN, first disable PIM on the interface.

PIM Neighbor Filters

The G8264CS accepts connection to up to 24 PIM interfaces. By default, the switch accepts all PIM neighbors attached to the PIM-enabled interfaces, up to the maximum number (72 neighbors). Once the maximum is reached, the switch will deny further PIM neighbors.

To ensure that only the appropriate PIM neighbors are accepted by the switch, the administrator can use PIM neighbor filters to specify which PIM neighbors may be accepted or denied on a per-interface basis.

To turn PIM neighbor filtering on or off for a particular IP interface, use the following commands:

```
RS 8264CS(config)# interface ip <Interface number>
RS 8264CS(config-ip-if)# [no] ip pim neighbor-filter
```

When filtering is enabled, all PIM neighbor requests on the specified IP interface will be denied by default. To allow a specific PIM neighbor, use the following command:

```
RS 8264CS(config-ip-if)# ip pim neighbor-addr <neighbor IPv4 address> allow
```

To remove a PIM neighbor from the accepted list, use the following command.

```
RS 8264CS(config-ip-if)# ip pim neighbor-addr <neighbor IPv4 address> deny
RS 8264CS(config-ip-if)# exit
```

You can view configured PIM neighbor filters globally or for a specific IP interface using the following commands:

```
RS 8264CS(config)# show ip pim neighbor-filters  
RS 8264CS(config)# show ip pim interface <Interface number> neighbor-filters
```

Additional Sparse Mode Settings

Specifying the Rendezvous Point

Using PIM-SM, at least one PIM-capable router must be a candidate for use as a Rendezvous Point (RP) for any given multicast group. If desired, the G8264CS can act as an RP candidate. To assign a configured switch IP interface as a candidate, use the following procedure.

1. Select the PIM component that will represent the RP candidate:

```
RS 8264CS(config)# ip pim component <1-2>
```

2. Configure the IPv4 address of the switch interface which will be advertised as a candidate RP for the specified multicast group:

```
RS 8264CS(config-ip-pim-comp)# rp-candidate rp-address <group address>  
<group address mask> <candidate IPv4 address>
```

The switch interface will participate in the election of the RP that occurs on the Bootstrap Router, or BSR (see [“Specifying a Bootstrap Router” on page 446](#)).

3. If using dynamic RP candidates, configure the amount of time that the elected interface will remain the RP for the group before a re-election is performed:

```
RS 8264CS(config-ip-pim-comp)# rp-candidate holdtime <0-255>  
RS 8264CS(config-ip-pim-comp)# exit
```

Static RP

If RP no election is desired, the switch can provide a static RP. Use the following commands:

1. Enable static RP configuration.

```
RS 8264CS(config)# ip pim static-rp enable
```

2. Select the PIM component that will represent the RP candidate:

```
RS 8264CS(config)# ip pim component <1-2>
```

3. Configure the static IPv4 address.

```
RS 8264CS(config-ip-pim-comp)# rp-static rp-address <group address>  
<group address mask> <static IPv4 address>
```

Influencing the Designated Router Selection

Using PIM-SM, All PIM-enabled IP interfaces are considered as potential Designate Routers (DR) for their domain. By default, the interface with the highest IP address on the domain is selected. However, if an interface is configured with a

DR priority value, it overrides the IP address selection process. If more than one interface on a domain is configured with a DR priority, the one with the highest number is selected.

Use the following commands to configure the DR priority value (Interface IP mode):

```
RS 8264CS(config)# interface ip <Interface number>
RS 8264CS(config-ip-if)# ip pim dr-priority <value (0-4294967294)>
RS 8264CS(config-ip-if)# exit
```

Note: A value of 0 (zero) specifies that the G8264CS will not act as the DR. This setting requires the G8264CS to be connected to a peer that has a DR priority setting of 1 or higher to ensure that a DR will be present in the network.

Specifying a Bootstrap Router

Using PIM-SM, a Bootstrap Router (BSR) is a PIM-capable router that hosts the election of the RP from available candidate routers. For each PIM-enabled IP interface, the administrator can set the preference level for which the local interface becomes the BSR:

```
RS 8264CS(config)# interface ip <Interface number>
RS 8264CS(config-ip-if)# ip pim cbsr-preference <0 to 255>
RS 8264CS(config-ip-if)# exit
```

A value of 255 highly prefers the local interface as a BSR. A value of 0 indicates that the PIM CBSR preference is not configured on the switch.

Configuring a Loopback Interface

Loopback interfaces can be used in PIM Sparse Mode for Rendezvous Points (RPs) and Bootstrap Routers (BSRs). For example:

- As a static RP

```
interface loopback 1
  ip address 55.55.1.1 255.255.255.0
  enable
  exit

ip pim static-rp enable

ip pim component 1
  rp-static rp-address 224.0.0.0 240.0.0.0 55.55.1.1

interface loopback 1
  ip pim enable
  exit
```

- As a candidate RP

```
interface loopback 1
  ip address 55.55.1.1 255.255.255.0
  enable
  exit

ip pim component 1
  rp-candidate holdtime 60
  rp-candidate rp-address 224.0.0.0 240.0.0.0 55.55.1.1

interface loopback 1
  ip pim enable
  exit
```

- As a BSR

```
interface loopback 1
  ip address 55.55.1.1 255.255.255.0
  enable
  exit

interface loopback 1
  ip pim enable
  ip pim cbsr-preference 2
  exit
```

Using PIM with Other Features

PIM with ACLs or VMAPs

If using ACLs or VMAPs, be sure to permit traffic for local hosts and routers.

PIM with IGMP

If using IGMP (see [“Internet Group Management Protocol” on page 353](#)):

- IGMP static joins can be configured with a PIM-SM or PIM-DM multicast group IPv4 address. Using the ISCLI:

```
RS 8264CS(config)# ip mroute <multicast group IPv4 address> <VLAN> <port>
```

- IGMP Querier is disabled by default. If IGMP Querier is needed with PIM, be sure to enable the IGMP Query feature globally, as well as on each VLAN where it is needed.
- If the switch is connected to multicast receivers and/or hosts, be sure to enable IGMP snooping globally, as well as on each VLAN where PIM receivers are attached.

PIM Configuration Examples

Example 1: PIM-SM with Dynamic RP

This example configures PIM Sparse Mode for one IP interface, with the switch acting as a candidate for dynamic Rendezvous Point (RP) selection.

1. Globally enable the PIM feature:

```
RS 8264CS(config)# ip pim enable
```

2. Configure a PIM network component with dynamic RP settings, and set it for PIM Sparse Mode:

```
RS 8264CS(config)# ip pim component 1
RS 8264CS(config-ip-pim-comp)# mode sparse
RS 8264CS(config-ip-pim-comp)# rp-candidate rp-address 225.1.0.0
255.255.0.0 10.10.1.1
RS 8264CS(config-ip-pim-comp)# rp-candidate holdtime <0-255>
RS 8264CS(config-ip-pim-comp)# exit
```

Where 225.1.0.0 is the multicast group base IP address, 255.255.0.0 is the multicast group address mask, and 10.10.1.1 is the switch RP candidate address.

Note: Because, Sparse Mode is set by default for PIM component 1, the `mode` command is needed only if the mode has been previously changed.

3. Define an IP interface for use with PIM:

```
RS 8264CS(config)# interface ip 111
RS 8264CS(config-ip-if)# ip address 10.10.1.1 255.255.255.255
RS 8264CS(config-ip-if)# vlan 11
RS 8264CS(config-ip-if)# enable
```

The IP interface represents the PIM network being connected to the switch. The IPv4 addresses in the defined range must not be included in another IP interface on the switch under a different VLAN.

4. Enable PIM on the IP interface and assign the PIM component:

```
RS 8264CS(config-ip-if)# ip pim enable
RS 8264CS(config-ip-if)# ip pim component-id 1
```

Note: Because, PIM component 1 is assigned to the interface by default, the `component -id` command is needed only if the setting has been previously changed.

5. Set the Bootstrap Router (BSR) preference:

```
RS 8264CS(config-ip-if)# ip pim cbsr-preference 135
RS 8264CS(config-ip-if)# exit
```

Example 2: PIM-SM with Static RP

The following commands can be used to modify the prior example configuration to use a static RP:

```
RS 8264CS(config)# ip pim static-rp enable
RS 8264CS(config)# ip pim component 1
RS 8264CS(config-ip-pim-comp)# rp-static rp-address 225.1.0.0 255.255.0.0
10.10.1.1
RS 8264CS(config-ip-pim-comp)# exit
```

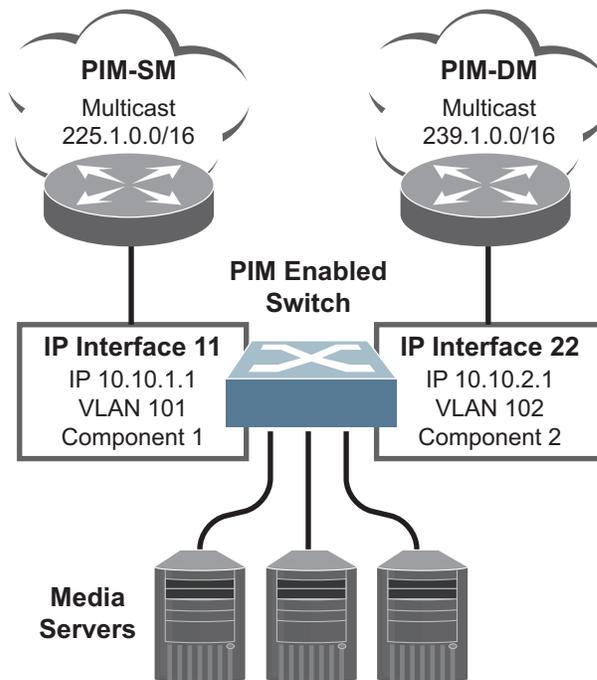

Where 225.1.0.0 255.255.0.0 is the multicast group base address and mask, and 10.10.1.1 is the static RP address.

Note: The same static RP address must be configured for all switches in the group.

Example 3: PIM-DM

This example configures PIM Dense Mode (PIM-DM) on one IP interface. PIM-DM can be configured independently, or it can be combined with the prior PIM-SM examples (which are configured on a different PIM component) as shown in [Figure 49](#).

Figure 49. Network with both PIM-DM and PIM-SM Components

1. Configure the PIM-SM component as shown in the prior examples, or if using PIM-DM independently, enable the PIM feature.

```
RS 8264CS(config)# ip pim enable
```

2. Configure a PIM component and set the PIM mode:

```
RS 8264CS(config)# ip pim component 2
RS 8264CS(config-ip-pim-comp)# mode dense
RS 8264CS(config-ip-pim-comp)# exit
```

3. Define an IP interface for use with PIM:

```
RS 8264CS(config)# interface ip 22
RS 8264CS(config-ip-if)# ip address 10.10.2.1 255.255.255.255
RS 8264CS(config-ip-if)# vlan 102
RS 8264CS(config-ip-if)# enable
```

4. Enable PIM on the IP interface and assign the PIM component:

```
RS 8264CS(config-ip-if)# ip pim enable
RS 8264CS(config-ip-if)# ip pim component-id 2
RS 8264CS(config-ip-if)# exit
```

5. (Optional) Configure PIM border router if the IPMC traffic is flowing between PIM domains:

```
RS 8264CS(config)# ip pim pmbr enable
RS 8264CS(config)# interface ip 22
RS 8264CS(config-ip-if)# ip pim border-bit
RS 8264CS(config-ip-if)# exit
```

Note: For PIM Dense Mode, the DR, RP, and BSR settings do not apply.

Part 6: High Availability Fundamentals

Internet traffic consists of myriad services and applications which use the Internet Protocol (IP) for data delivery. However, IP is not optimized for all the various applications. High Availability goes beyond IP and makes intelligent switching decisions to provide redundant network configurations.

Chapter 30. Basic Redundancy

Lenovo Networking OS 8.2 includes various features for providing basic link or device redundancy:

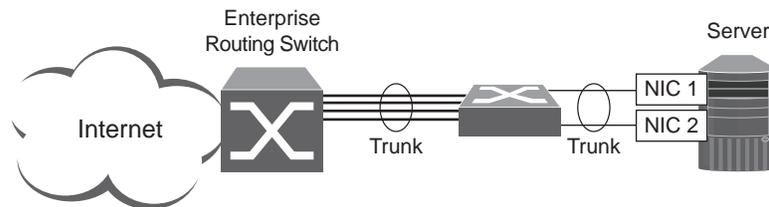

- [“Trunking for Link Redundancy” on page 456](#)
- [“Virtual Link Aggregation” on page 456](#)
- [“Hot Links” on page 457](#)

Trunking for Link Redundancy

Multiple switch ports can be combined together to form robust, high-bandwidth trunks to other devices. Since trunks are comprised of multiple physical links, the trunk group is inherently fault tolerant. As long as one connection between the switches is available, the trunk remains active.

In [Figure 50](#), four ports are trunked together between the switch and the enterprise routing device. Connectivity is maintained as long as one of the links remain active. The links to the server are also trunked, allowing the secondary NIC to take over in the event that the primary NIC link fails.

Figure 50. Trunking Ports for Link Redundancy

For more information on trunking, see [“Ports and Trunking” on page 141](#).

Virtual Link Aggregation

Using the VLAG feature, switches can be paired as VLAG peers. The peer switches appear to the connecting device as a single virtual entity for the purpose of establishing a multi-port trunk. The VLAG-capable switches synchronize their logical view of the access layer port structure and internally prevent implicit loops. The VLAG topology also responds more quickly to link failure and does not result in unnecessary MAC flooding.

VLAGs are useful in multi-layer environments for both uplink and downlink redundancy to any regular LAG-capable device. They can also be used in for active-active VRRP connections.

For more information on VLAGs, see [“Virtual Link Aggregation Groups” on page 175](#).

Hot Links

Hot Links provides basic link redundancy with fast recovery.

Hot Links consists of up to 25 triggers. A trigger consists of a pair of layer 2 interfaces, each containing an individual port, trunk, or LACP adminkey. One interface is the Master, and the other is a Backup. While the Master interface is set to the active state and forwards traffic, the Backup interface is set to the standby state and blocks traffic until the Master interface fails. If the Master interface fails, the Backup interface is set to active and forwards traffic. Once the Master interface is restored, it regains its active state and forwards traffic. The Backup transitions to the standby state.

You may select a physical port, static trunk, or an LACP adminkey as a Hot Link interface.

Forward Delay

The Forward Delay timer allows Hot Links to monitor the Master and Backup interfaces for link stability before selecting one interface to transition to the active state. Before the transition occurs, the interface must maintain a stable link for the duration of the Forward Delay interval.

For example, if you set the Forward delay timer to 10 seconds, the switch will select an interface to become active only if a link remained stable for the duration of the Forward Delay period. If the link is unstable, the Forward Delay period starts again.

Preemption

You can configure the Master interface to resume the active state whenever it becomes available. With Hot Links preemption enabled, the Master interface transitions to the active state immediately upon recovery. The Backup interface immediately transitions to the standby state. If Forward Delay is enabled, the transition occurs when an interface has maintained link stability for the duration of the Forward Delay period.

FDB Update

Use the FDB update option to notify other devices on the network about updates to the Forwarding Database (FDB). When you enable FDB update, the switch sends multicasts of addresses in the forwarding database (FDB) over the active interface, so that other devices on the network can learn the new path. The Hot Links FDB update option uses the station update rate to determine the rate at which to send FDB packets.

Configuration Guidelines

The following configuration guidelines apply to Hot links:

- When Hot Links is turned on, STP must be turned off on the Hot Links ports.

- A port that is a member of the Master interface cannot be a member of the Backup interface. A port that is a member of one Hot Links trigger cannot be a member of another Hot Links trigger.
- An individual port that is configured as a Hot Link interface cannot be a member of a trunk.

Configuring Hot Links

Use the following commands to configure Hot Links.

```
RS 8264CS(config)# hotlinks trigger 1 enable (Enable Hot Links Trigger 1)  
RS 8264CS(config)# hotlinks trigger 1 master port 1 (Add port to Master interface)  
RS 8264CS(config)# hotlinks trigger 1 backup port 2 (Add port to Backup interface)  
RS 8264CS(config)# hotlinks enable (Turn on Hot Links)
```

Chapter 31. Layer 2 Failover

The primary application for Layer 2 Failover is to support Network Adapter Teaming. With Network Adapter Teaming, all the NICs on each server share the same IP address, and are configured into a team. One NIC is the primary link, and the other is a standby link. For more details, refer to the documentation for your Ethernet adapter.

Note: Only two links per server can be used for Layer 2 Trunk Failover (one primary and one backup). Network Adapter Teaming allows only one backup NIC for each server blade.

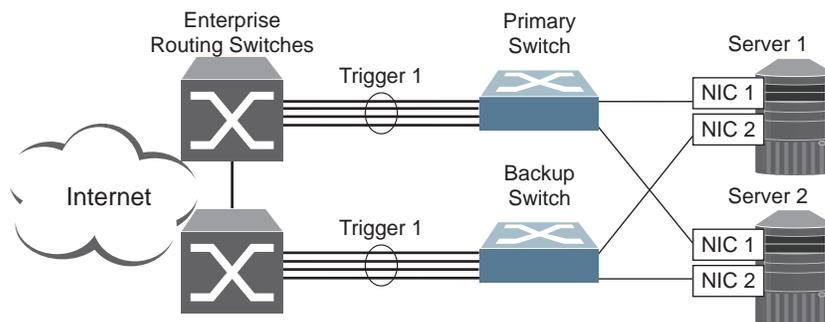

Monitoring Trunk Links

Layer 2 Failover can be enabled on any trunk group in the G8264CS, including LACP trunks. Trunks can be added to failover trigger groups. Then, if some specified number of monitor links fail, the switch disables all the control ports in the switch. When the control ports are disabled, it causes the NIC team on the affected servers to failover from the primary to the backup NIC. This process is called a failover event.

When the appropriate number of links in a monitor group return to service, the switch enables the control ports. This causes the NIC team on the affected servers to fail back to the primary switch (unless Auto-Fallback is disabled on the NIC team). The backup switch processes traffic until the primary switch's control links come up, which can take up to five seconds.

Figure 51 is a simple example of Layer 2 Failover. One G8264CS is the primary, and the other is used as a backup. In this example, all ports on the primary switch belong to a single trunk group, with Layer 2 Failover enabled, and Failover Limit set to 2. If two or fewer links in trigger 1 remain active, the switch temporarily disables all control ports. This action causes a failover event on Server 1 and Server 2.

Figure 51. Basic Layer 2 Failover

Setting the Failover Limit

The failover limit lets you specify the minimum number of operational links required within each trigger before the trigger initiates a failover event. For example, if the limit is two, a failover event occurs when the number of operational links in the trigger is two or fewer. When you set the limit to zero, the switch triggers a failover event only when no links in the trigger are operational.

Manually Monitoring Port Links

The Manual Monitor allows you to configure a set of ports and trunks to monitor for link failures (a monitor list), and another set of ports and trunks to disable when the trigger limit is reached (a control list). When the switch detects a link failure on the monitor list, it automatically disables the items in control list. When server ports are disabled, the corresponding server's network adapter can detect the disabled link, and trigger a network-adapter failover to another port or trunk on the switch, or another switch.

The switch automatically enables the control list items when the monitor list items return to service.

Monitor Port State

A monitor port is considered operational as long as the following conditions are true:

- The port must be in the `Link Up` state.
- If STP is enabled, the port must be in the `Forwarding` state.
- If the port is part of an LACP trunk, the port must be in the `Aggregated` state.

If any of these conditions is false, the monitor port is considered to have failed.

Control Port State

A control port is considered Operational if the monitor trigger is up. As long as the trigger is up, the port is considered operational from a teaming perspective, even if the port itself is actually in the `Down` state, `Blocking` state (if STP is enabled on the port), or `Not Aggregated` state (if part of an LACP trunk).

A control port is considered to have failed only if the monitor trigger is in the `Down` state.

To view the state of any port, use one of the following commands:

```
>> # show interface link                (View port link status)
>> # show interface port <x> spanning-tree stp <x> (View port STP status)
>> # show lacp information                (View port LACP status)
```

L2 Failover with Other Features

L2 Failover works together with static trunks, Link Aggregation Control Protocol (LACP), and with Spanning Tree Protocol (STP), as described in the next sections.

Static Trunks

When you add a portchannel (static trunk group) to a failover trigger, any ports in that trunk become members of the trigger. You can add up to 64 static trunks to a failover trigger, using manual monitoring.

LACP

Link Aggregation Control Protocol allows the switch to form dynamic trunks. You can use the *admin key* to add up to two LACP trunks to a failover trigger using automatic monitoring. When you add an *admin key* to a trigger, any LACP trunk with that *admin key* becomes a member of the trigger.

Spanning Tree Protocol

If Spanning Tree Protocol (STP) is enabled on the ports in a failover trigger, the switch monitors the port STP state rather than the link state. A port failure results when STP is not in a Forwarding state (such as Learning, Discarding, or No Link) in all the Spanning Tree Groups (STGs) to which the port belongs. The switch automatically disables the appropriate control ports.

When the switch determines that ports in the trigger are in STP Forwarding state in any one of the STGs it belongs to, then it automatically enables the appropriate control ports. The switch *fails back* to normal operation.

For example, if a monitor port is a member of STG1, STG2, and STG3, a failover will be triggered only if the port is not in a forwarding state in all the three STGs. When the port state in any of the three STGs changes to forwarding, then the control port is enabled and normal switch operation is resumed.

Configuration Guidelines

This section provides important information about configuring Layer 2 Failover.

- Any specific failover trigger can monitor ports only, static trunks only, or LACP trunks only. The different types cannot be combined in the same trigger.
- A maximum of 64 LACP keys can be added per trigger.
- Management ports cannot be monitored.
- Control ports for different triggers must not overlap. Monitor ports may overlap.

Configuring Layer 2 Failover

Use the following procedure to configure a Layer 2 Failover Manual Monitor.

1. Specify the links to monitor.

```
RS 8264CS(config)# failover trigger 1 mmon monitor member 1-5
```

2. Specify the links to disable when the failover limit is reached.

```
RS 8264CS(config)# failover trigger 1 mmon control member 6-10
```

3. Configure general Failover parameters.

```
RS 8264CS(config)# failover enable
RS 8264CS(config)# failover trigger 1 enable
RS 8264CS(config)# failover trigger 1 limit 2
```

Chapter 32. Virtual Router Redundancy Protocol

The RackSwitch G8264CS (G8264CS) supports IPv4 high-availability network topologies through an enhanced implementation of the Virtual Router Redundancy Protocol (VRRP).

Note: Lenovo Networking OS 8.2 does not support IPv6 for VRRP.

The following topics are discussed in this chapter:

- [“VRRP Overview” on page 466](#). This section discusses VRRP operation and Lenovo N/OS redundancy configurations.
- [“Failover Methods” on page 469](#). This section describes the three modes of high availability.
- [“Lenovo N/OS Extensions to VRRP” on page 470](#). This section describes VRRP enhancements implemented in N/OS.
- [“Virtual Router Deployment Considerations” on page 471](#). This section describes issues to consider when deploying virtual routers.
- [“High Availability Configurations” on page 472](#). This section discusses the more useful and easily deployed redundant configurations.

VRRP Overview

In a high-availability network topology, no device can create a single point-of-failure for the network or force a single point-of-failure to any other part of the network. This means that your network will remain in service despite the failure of any single device. To achieve this usually requires redundancy for all vital network components.

VRRP enables redundant router configurations within a LAN, providing alternate router paths for a host to eliminate single points-of-failure within a network. Each participating VRRP-capable routing device is configured with the same virtual router IPv4 address and ID number. One of the virtual routers is elected as the master, based on a number of priority criteria, and assumes control of the shared virtual router IPv4 address. If the master fails, one of the backup virtual routers will take control of the virtual router IPv4 address and actively process traffic addressed to it.

With VRRP, Virtual Interface Routers (VIR) allow two VRRP routers to share an IP interface across the routers. VIRs provide a single Destination IPv4 (DIP) address for upstream routers to reach various servers, and provide a virtual default Gateway for the servers.

VRRP Components

Each physical router running VRRP is known as a *VRRP router*.

Virtual Router

Two or more VRRP routers can be configured to form a *virtual router* (RFC 2338). Each VRRP router may participate in one or more virtual routers. Each virtual router consists of a user-configured *virtual router identifier* (VRID) and an IPv4 address.

Virtual Router MAC Address

The VRID is used to build the *virtual router MAC Address*. The five highest-order octets of the virtual router MAC Address are the standard MAC prefix (00-00-5E-00-01) defined in RFC 2338. The VRID is used to form the lowest-order octet.

Owners and Renters

Only one of the VRRP routers in a virtual router may be configured as the IPv4 address owner. This router has the virtual router's IPv4 address as its real interface address. This router responds to packets addressed to the virtual router's IPv4 address for ICMP pings, TCP connections, and so on.

There is no requirement for any VRRP router to be the IPv4 address owner. Most VRRP installations choose not to implement an IPv4 address owner. For the purposes of this chapter, VRRP routers that are not the IPv4 address owner are called *renters*.

Master and Backup Virtual Router

Within each virtual router, one VRRP router is selected to be the virtual router master. See [“Selecting the Master VRRP Router” on page 468](#) for an explanation of the selection process.

Note: If the IPv4 address owner is available, it will always become the virtual router master.

The virtual router master forwards packets sent to the virtual router. It also responds to Address Resolution Protocol (ARP) requests sent to the virtual router's IPv4 address. Finally, the virtual router master sends out periodic advertisements to let other VRRP routers know it is alive and its priority.

Within a virtual router, the VRRP routers not selected to be the master are known as virtual router backups. If the virtual router master fails, one of the virtual router backups becomes the master and assumes its responsibilities.

Virtual Interface Router

At Layer 3, a Virtual Interface Router (VIR) allows two VRRP routers to share an IP interface across the routers. VIRs provide a single Destination IPv4 (DIP) address for upstream routers to reach various destination networks, and provide a virtual default Gateway.

Note: Every VIR must be assigned to an IP interface, and every IP interface must be assigned to a VLAN. If no port in a VLAN has link up, the IP interface of that VLAN is down, and if the IP interface of a VIR is down, that VIR goes into INIT state.

VRRP Operation

Only the virtual router master responds to ARP requests. Therefore, the upstream routers only forward packets destined to the master. The master also responds to ICMP ping requests. The backup does not forward any traffic, nor does it respond to ARP requests.

If the master is not available, the backup becomes the master and takes over responsibility for packet forwarding and responding to ARP requests.

Selecting the Master VRRP Router

Each VRRP router is configured with a priority between 1–254. A bidding process determines which VRRP router is or becomes the master—the VRRP router with the highest priority.

The master periodically sends advertisements to an IPv4 multicast address. As long as the backups receive these advertisements, they remain in the backup state. If a backup does not receive an advertisement for three advertisement intervals, it initiates a bidding process to determine which VRRP router has the highest priority and takes over as master. In addition to the three advertisement intervals, a manually set holdoff time can further delay the backups from assuming the master status.

If, at any time, a backup determines that it has higher priority than the current master does, it can preempt the master and become the master itself, unless configured not to do so. In preemption, the backup assumes the role of master and begins to send its own advertisements. The current master sees that the backup has higher priority and will stop functioning as the master.

A backup router can stop receiving advertisements for one of two reasons—the master can be down, or all communications links between the master and the backup can be down. If the master has failed, it is clearly desirable for the backup (or one of the backups, if there is more than one) to become the master.

Note: If the master is healthy but communication between the master and the backup has failed, there will then be two masters within the virtual router. To prevent this from happening, configure redundant links to be used between the switches that form a virtual router.

Failover Methods

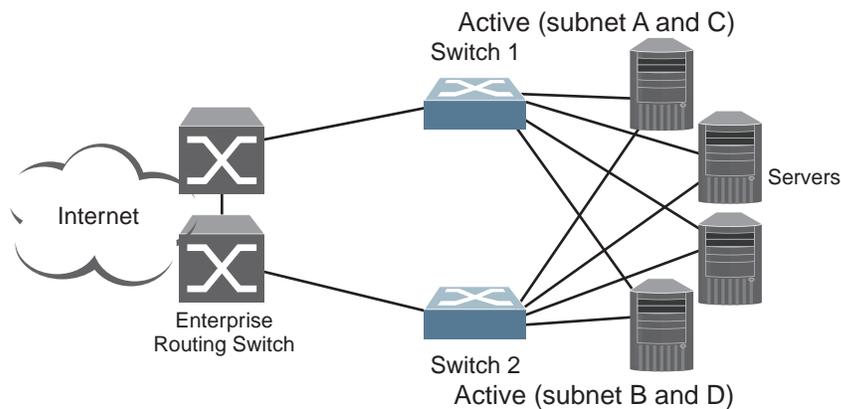

With service availability becoming a major concern on the Internet, service providers are increasingly deploying Internet traffic control devices, such as application switches, in redundant configurations. N/OS high availability configurations are based on VRRP. The N/OS implementation of VRRP includes proprietary extensions.

Active-Active Redundancy

In an active-active configuration, shown in [Figure 52](#), two switches provide redundancy for each other, with both active at the same time. Each switch processes traffic on a different subnet. When a failure occurs, the remaining switch can process traffic on all subnets.

For a configuration example, see [“High Availability Configurations” on page 472](#).

Figure 52. Active-Active Redundancy

Virtual Router Group

The virtual router group ties all virtual routers on the switch together as a single entity. As members of a group, all virtual routers on the switch (and therefore the switch itself), are in either a master or standby state.

A VRRP group has the following characteristics:

- When enabled, all virtual routers behave as one entity, and all group settings override any individual virtual router settings.
- All individual virtual routers, once the VRRP group is enabled, assume the group's tracking and priority.
- When one member of a VRRP group fails, the priority of the group decreases, and the state of the entire switch changes from Master to Standby.

Each VRRP advertisement can include up to 16 addresses. All virtual routers are advertised within the same packet, conserving processing and buffering resources.

Lenovo N/OS Extensions to VRRP

This section describes VRRP enhancements that are implemented in N/OS.

N/OS supports a tracking function that dynamically modifies the priority of a VRRP router, based on its current state. The objective of tracking is to have, whenever possible, the master bidding processes for various virtual routers in a LAN converge on the same switch. Tracking ensures that the selected switch is the one that offers optimal network performance. For tracking to have any effect on virtual router operation, preemption must be enabled.

N/OS can track the attributes listed in [Table 36](#) (Router VRRP mode):

Table 36. *VRRP Tracking Parameters*

Parameter	Description
Number of IP interfaces on the switch that are active (“up”) tracking-priority-increment interfaces	Helps elect the virtual routers with the most available routes as the master. (An IP interface is considered active when there is at least one active port on the same VLAN.) This parameter influences the VRRP router's priority in virtual interface routers.
Number of active ports on the same VLAN tracking-priority-increment ports	Helps elect the virtual routers with the most available ports as the master. This parameter influences the VRRP router's priority in virtual interface routers.
Number of virtual routers in master mode on the switch tracking-priority-increment virtual-routers	Useful for ensuring that traffic for any particular client/server pair is handled by the same switch, increasing routing efficiency. This parameter influences the VRRP router's priority in virtual interface routers.

Each tracked parameter has a user-configurable weight associated with it. As the count associated with each tracked item increases (or decreases), so does the VRRP router's priority, subject to the weighting associated with each tracked item. If the priority level of a standby is greater than that of the current master, then the standby can assume the role of the master.

See [“Configuring the Switch for Tracking” on page 471](#) for an example on how to configure the switch for tracking VRRP priority.

Virtual Router Deployment Considerations

Assigning VRRP Virtual Router ID

During the software upgrade process, VRRP virtual router IDs will be automatically assigned if failover is enabled on the switch. When configuring virtual routers at any point after upgrade, virtual router ID numbers must be assigned. The virtual router ID may be configured as any number between 1 and 128. Use the following command to configure the virtual router ID:

```
RS 8264CS(config)# router vrrp
RS 8264CS(config-vrrp)# virtual-router 1 virtual-router-id <1-128>
```

Configuring the Switch for Tracking

Tracking configuration largely depends on user preferences and network environment. Consider the configuration shown in [Figure 52 on page 469](#). Assume the following behavior on the network:

- Switch 1 is the master router upon initialization.
- If switch 1 is the master and it has one fewer active servers than switch 2, then switch 1 remains the master.
This behavior is preferred because running one server down is less disruptive than bringing a new master online and severing all active connections in the process.
- If switch 1 is the master and it has two or more active servers fewer than switch 2, then switch 2 becomes the master.
- If switch 2 is the master, it remains the master even if servers are restored on switch 1 such that it has one fewer or an equal number of servers.
- If switch 2 is the master and it has one active server fewer than switch 1, then switch 1 becomes the master.

You can implement this behavior by configuring the switch for tracking as follows:

1. Set the priority for switch 1 to 101.
2. Leave the priority for switch 2 at the default value of 100.
3. On both switches, enable tracking based on ports, interfaces, or virtual routers. You can choose any combination of tracking parameters, based on your network configuration.

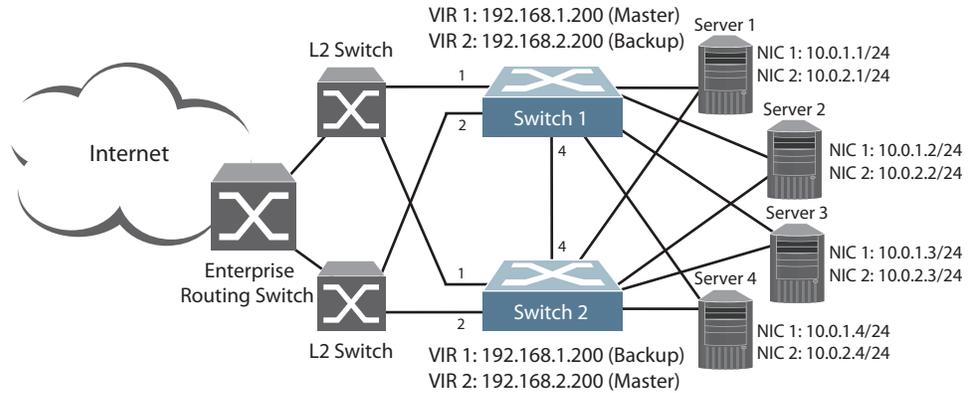

Note: There is no shortcut to setting tracking parameters. The goals must first be set and the outcomes of various configurations and scenarios analyzed to find settings that meet the goals.

High Availability Configurations

VRRP High-Availability Using Multiple VIRs

Figure 53 shows an example configuration where two G8264CSs are used as VRRP routers in an active-active configuration. In this configuration, both switches respond to packets.

Figure 53. Active-Active Configuration using VRRP

Although this example shows only two switches, there is no limit on the number of switches used in a redundant configuration. It is possible to implement an active-active configuration across all the VRRP-capable switches in a LAN.

Each VRRP-capable switch in an active-active configuration is autonomous. Switches in a virtual router need not be identically configured.

In the scenario illustrated in Figure 53, traffic destined for IPv4 address 10.0.1.1 is forwarded through the Layer 2 switch at the top of the drawing, and ingresses G8264CS 1 on port 1. Return traffic uses default gateway 1 (192.168.1.1), which must be in the same network.

If the link between G8264CS 1 and the Layer 2 switch fails, G8264CS 2 becomes the Master because it has a higher priority. Traffic is forwarded to G8264CS 2, which forwards it to G8264CS 1 through port 4. Return traffic uses default gateway 2 (192.168.2.2), and is forwarded through the Layer 2 switch at the bottom of the drawing.

To implement the active-active example, perform the following switch configuration.

Task 1: Configure G8264CS 1

1. Configure client and server interfaces.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 192.168.1.100 255.255.255.0
RS 8264CS(config-ip-if)# vlan 10
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 192.168.2.101 255.255.255.0
RS 8264CS(config-ip-if)# vlan 20
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 10.0.1.100 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 4
RS 8264CS(config-ip-if)# ip address 10.0.2.101 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Configure the default gateways. Each default gateway points to a Layer 3 router.

```
RS 8264CS(config)# ip gateway 1 address 192.168.1.1
RS 8264CS(config)# ip gateway 1 enable
RS 8264CS(config)# ip gateway 2 address 192.168.2.1
RS 8264CS(config)# ip gateway 2 enable
```

3. Turn on VRRP and configure two Virtual Interface Routers.

```
RS 8264CS(config)# router vrrp
RS 8264CS(config-vrrp)# enable
RS 8264CS(config-vrrp)# virtual-router 1 virtual-router-id 1
RS 8264CS(config-vrrp)# virtual-router 1 interface 1
RS 8264CS(config-vrrp)# virtual-router 1 address 192.168.1.200
RS 8264CS(config-vrrp)# virtual-router 1 enable
RS 8264CS(config-vrrp)# virtual-router 2 virtual-router-id 2
RS 8264CS(config-vrrp)# virtual-router 2 interface 2
RS 8264CS(config-vrrp)# virtual-router 2 address 192.168.2.200
RS 8264CS(config-vrrp)# virtual-router 2 enable
```

4. Enable tracking on ports. Set the priority of Virtual Router 1 to 101, so that it becomes the Master.

```
RS 8264CS(config-vrrp)# virtual-router 1 track ports
RS 8264CS(config-vrrp)# virtual-router 1 priority 101
RS 8264CS(config-vrrp)# virtual-router 2 track ports
RS 8264CS(config-vrrp)# exit
```

5. Configure ports.

```
RS 8264CS(config)# vlan 10
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 10
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 20
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 20
RS 8264CS(config-if)# exit
```

6. Turn off Spanning Tree Protocol globally.

```
RS 8264CS(config)# no spanning-tree stp 1
```

Task 2: Configure G8264CS 2

1. Configure client and server interfaces.

```
RS 8264CS(config)# interface ip 1
RS 8264CS(config-ip-if)# ip address 192.168.1.101 255.255.255.0
RS 8264CS(config-ip-if)# vlan 10
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 2
RS 8264CS(config-ip-if)# ip address 192.168.2.100 255.255.255.0
RS 8264CS(config-ip-if)# vlan 20
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 3
RS 8264CS(config-ip-if)# ip address 10.0.1.101 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
RS 8264CS(config)# interface ip 4
RS 8264CS(config-ip-if)# ip address 10.0.2.100 255.255.255.0
RS 8264CS(config-ip-if)# enable
RS 8264CS(config-ip-if)# exit
```

2. Configure the default gateways. Each default gateway points to a Layer 3 router.

```
RS 8264CS(config)# ip gateway 1 address 192.168.2.1
RS 8264CS(config)# ip gateway 1 enable
RS 8264CS(config)# ip gateway 2 address 192.168.1.1
RS 8264CS(config)# ip gateway 2 enable
```

3. Turn on VRRP and configure two Virtual Interface Routers.

```
RS 8264CS(config)# router vrrp
RS 8264CS(config-vrrp)# enable
RS 8264CS(config-vrrp)# virtual-router 1 virtual-router-id 1
RS 8264CS(config-vrrp)# virtual-router 1 interface 1
RS 8264CS(config-vrrp)# virtual-router 1 address 192.168.1.200
RS 8264CS(config-vrrp)# virtual-router 1 enable
RS 8264CS(config-vrrp)# virtual-router 2 virtual-router-id 2
RS 8264CS(config-vrrp)# virtual-router 2 interface 2
RS 8264CS(config-vrrp)# virtual-router 2 address 192.168.2.200
RS 8264CS(config-vrrp)# virtual-router 2 enable
```

4. Enable tracking on ports. Set the priority of Virtual Router 2 to 101, so that it becomes the Master.

```
RS 8264CS(config-vrrp)# virtual-router 1 track ports
RS 8264CS(config-vrrp)# virtual-router 2 track ports
RS 8264CS(config-vrrp)# virtual-router 2 priority 101
RS 8264CS(config-vrrp)# exit
```

5. Configure ports.

```
RS 8264CS(config)# vlan 10
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 10
RS 8264CS(config-if)# exit

RS 8264CS(config)# vlan 20
RS 8264CS(config-vlan)# exit
RS 8264CS(config)# interface port 2
RS 8264CS(config-if)# switchport mode trunk
RS 8264CS(config-if)# switchport trunk allowed vlan add 20
RS 8264CS(config-if)# exit
```

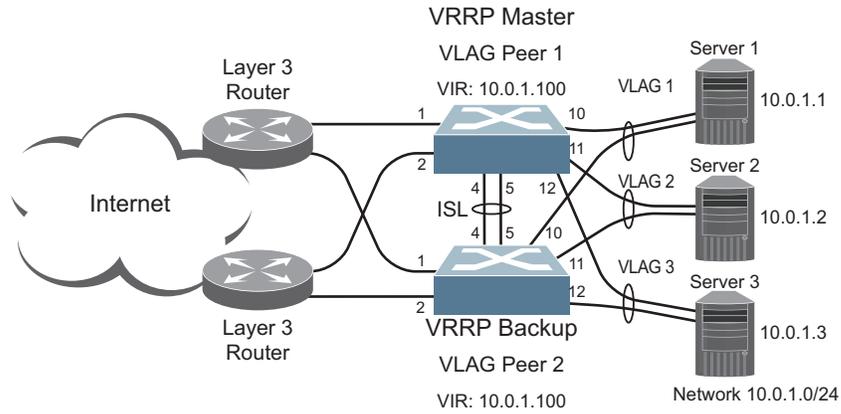

6. Turn off Spanning Tree Protocol globally.

```
RS 8264CS(config)# no spanning-tree stp 1
```

VRRP High-Availability Using VLAGs

VRRP can be used in conjunction with VLAGs and LACP-capable servers and switches to provide seamless redundancy.

Figure 54. Active-Active Configuration using VRRP and VLAGs

See [“VLAGs with VRRP”](#) on page 185 for a detailed configuration example.

Part 7: Network Management

Chapter 33. Link Layer Discovery Protocol

The Lenovo Networking OS software support Link Layer Discovery Protocol (LLDP). This chapter discusses the use and configuration of LLDP on the switch:

- [“LLDP Overview” on page 480](#)
- [“Enabling or Disabling LLDP” on page 481](#)
- [“LLDP Transmit Features” on page 482](#)
- [“LLDP Receive Features” on page 486](#)
- [“LLDP Example Configuration” on page 490](#)

LLDP Overview

Link Layer Discovery Protocol (LLDP) is an IEEE 802.1AB-2005 standard for discovering and managing network devices. LLDP uses Layer 2 (the data link layer), and allows network management applications to extend their awareness of the network by discovering devices that are direct neighbors of already known devices.

With LLDP, the G8264CS can advertise the presence of its ports, their major capabilities, and their current status to other LLDP stations in the same LAN. LLDP transmissions occur on ports at regular intervals or whenever there is a relevant change to their status. The switch can also receive LLDP information advertised from adjacent LLDP-capable network devices.

In addition to discovery of network resources, and notification of network changes, LLDP can help administrators quickly recognize a variety of common network configuration problems, such as unintended VLAN exclusions or mis-matched port aggregation membership.

The LLDP transmit function and receive function can be independently configured on a per-port basis. The administrator can allow any given port to transmit only, receive only, or both transmit and receive LLDP information.

The LLDP information to be distributed by the G8264CS ports, and that which has been collected from other LLDP stations, is stored in the switch's Management Information Base (MIB). Network Management Systems (NMS) can use Simple Network Management Protocol (SNMP) to access this MIB information. LLDP-related MIB information is read-only.

Changes, either to the local switch LLDP information or to the remotely received LLDP information, are flagged within the MIB for convenient tracking by SNMP-based management systems.

For LLDP to provide expected benefits, all network devices that support LLDP must be consistent in their LLDP configuration.

Enabling or Disabling LLDP

Global LLDP Setting

By default, LLDP is enabled on the G8264CS. To turn LLDP on or off, use the following command:

```
RS 8264CS(config)# [no] lldp enable    (Turn LLDP on or off globally)
```

Transmit and Receive Control

The G8264CS can also be configured to transmit or receive LLDP information on a port-by-port basis. By default, when LLDP is globally enabled on the switch, G8264CS ports transmit and receive LLDP information (see the `tx_rx` option in the following example). To change the LLDP transmit and receive state, the following commands are available:

```
RS 8264CS(config)# interface port 1    (Select a switch port)  
RS 8264CS(config-if)# lldp admin-status tx_rx (Transmit and receive LLDP)  
RS 8264CS(config-if)# lldp admin-status tx_only (Only transmit LLDP)  
RS 8264CS(config-if)# lldp admin-status rx_only (Only receive LLDP)  
RS 8264CS(config-if)# no lldp admin-status (Do not participate in LLDP)  
RS 8264CS(config-if)# exit             (Exit port mode)
```

To view the LLDP transmit and receive status, use the following commands:

```
RS 8264CS(config)# show lldp port      (status of all ports)  
RS 8264CS(config)# show interface port <n> lldp (status of selected port)
```

LLDP Transmit Features

Numerous LLDP transmit options are available, including scheduled and minimum transmit interval, expiration on remote systems, SNMP trap notification, and the types of information permitted to be shared.

Scheduled Interval

The G8264CS can be configured to transmit LLDP information to neighboring devices once each 5 to 32768 seconds. The scheduled interval is global; the same interval value applies to all LLDP transmit-enabled ports. However, to help balance LLDP transmissions and keep them from being sent simultaneously on all ports, each port maintains its own interval clock, based on its own initialization or reset time. This allows switch-wide LLDP transmissions to be spread out over time, though individual ports comply with the configured interval.

The global transmit interval can be configured using the following command:

```
RS 8264CS(config)# lldp refresh-interval <interval>
```

where *interval* is the number of seconds between LLDP transmissions. The range is 5 to 32768. The default is 30 seconds.

Minimum Interval

In addition to sending LLDP information at scheduled intervals, LLDP information is also sent when the G8264CS detects relevant changes to its configuration or status (such as when ports are enabled or disabled). To prevent the G8264CS from sending multiple LLDP packets in rapid succession when port status is in flux, a transmit delay timer can be configured.

The transmit delay timer represents the minimum time permitted between successive LLDP transmissions on a port. Any interval-driven or change-driven updates will be consolidated until the configured transmit delay expires.

The minimum transmit interval can be configured using the following command:

```
RS 8264CS(config)# lldp transmission-delay <interval>
```

where *interval* is the minimum number of seconds permitted between successive LLDP transmissions on any port. The range is 1 to one-quarter of the scheduled transmit interval (`lldp refresh-interval <value>`), up to 8192. The default is 2 seconds.

Time-to-Live for Transmitted Information

The transmitted LLDP information is held by remote systems for a limited time. A time-to-live parameter allows the switch to determine how long the transmitted data is held before it expires. The hold time is configured as a multiple of the configured transmission interval.

```
RS 8264CS(config)# lldp holdtime-multiplier <multiplier>
```

where *multiplier* is a value between 2 and 10. The default value is 4, meaning that remote systems will hold the port's LLDP information for 4 x the 30-second transmission interval value, or 120 seconds, before removing it from their MIB.

Trap Notifications

If SNMP is enabled on the G8264CS (see [“Using Simple Network Management Protocol” on page 36](#)), each port can be configured to send SNMP trap notifications whenever LLDP transmissions are sent. By default, trap notification is disabled for each port. The trap notification state can be changed using the following commands (Interface Port mode):

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# [no] lldp trap-notification
RS 8264CS(config-if)# exit
```

In addition to sending LLDP information at scheduled intervals, LLDP information is also sent when the G8264CS detects relevant changes to its configuration or status (such as when ports are enabled or disabled). To prevent the G8264CS from sending multiple trap notifications in rapid succession when port status is in flux, a global trap delay timer can be configured.

The trap delay timer represents the minimum time permitted between successive trap notifications on any port. Any interval-driven or change-driven trap notices from the port will be consolidated until the configured trap delay expires.

The minimum trap notification interval can be configured using the following command:

```
RS 8264CS(config)# lldp trap-notification-interval <interval>
```

where *interval* is the minimum number of seconds permitted between successive LLDP transmissions on any port. The range is 1 to 3600. The default is 5 seconds.

If SNMP trap notification is enabled, the notification messages can also appear in the system log. This is enabled by default. To change whether the SNMP trap notifications for LLDP events appear in the system log, use the following command:

```
RS 8264CS(config)# [no] logging log lldp
```

Changing the LLDP Transmit State

When the port is disabled, or when LLDP transmit is turned off for the port using the LLDP admin-status command options (see [“Transmit and Receive Control” on page 481](#)), a final LLDP packet is transmitted with a time-to-live value of 0. Neighbors that receive this packet will remove the LLDP information associated with the G8264CS port from their MIB.

In addition, if LLDP is fully disabled on a port and then later re-enabled, the G8264CS will temporarily delay resuming LLDP transmissions on the port to allow the port LLDP information to stabilize. The reinitialization delay interval can be globally configured for all ports using the following command:

```
RS 8264CS(config)# lldp reinit-delay <interval>
```

where *interval* is the number of seconds to wait before resuming LLDP transmissions. The range is between 1 and 10. The default is 2 seconds.

Types of Information Transmitted

When LLDP transmission is permitted on the port (see [“Enabling or Disabling LLDP” on page 481](#)), the port advertises the following required information in type/length/value (TLV) format:

- Chassis ID
- Port ID
- LLDP Time-to-Live

LLDP transmissions can also be configured to enable or disable inclusion of optional information, using the following command (Interface Port mode):

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# [no] lldp tlv <type>
RS 8264CS(config-if)# exit
```

where *type* is an LLDP information option from [Table 37](#):

Table 37. LLDP Optional Information Types

Type	Description	Default
portdesc	Port Description	Enabled
sysname	System Name	Enabled
sysdescr	System Description	Enabled
syscap	System Capabilities	Enabled
mgmtaddr	Management Address	Enabled
portvid	IEEE 802.1 Port VLAN ID	Disabled
portprot	IEEE 802.1 Port and Protocol VLAN ID	Disabled
vlanname	IEEE 802.1 VLAN Name	Disabled
protid	IEEE 802.1 Protocol Identity	Disabled
macphy	IEEE 802.3 MAC/PHY Configuration/Status, including the auto-negotiation, duplex, and speed status of the port.	Disabled

Table 37. *LLDP Optional Information Types (continued)*

Type	Description	Default
powermdi	IEEE 802.3 Power via MDI, indicating the capabilities and status of devices that require or provide power over twisted-pair copper links.	Disabled
linkaggr	IEEE 802.3 Link Aggregation status for the port.	Disabled
framesz	IEEE 802.3 Maximum Frame Size for the port.	Disabled
all	Select all optional LLDP information for inclusion or exclusion.	Disabled

LLDP Receive Features

Types of Information Received

When the LLDP receive option is enabled on a port (see [“Enabling or Disabling LLDP” on page 481](#)), the port may receive the following information from LLDP-capable remote systems:

- Chassis Information
- Port Information
- LLDP Time-to-Live
- Port Description
- System Name
- System Description
- System Capabilities Supported/Enabled
- Remote Management Address

The G8264CS stores the collected LLDP information in the MIB. Each remote LLDP-capable device is responsible for transmitting regular LLDP updates. If the received updates contain LLDP information changes (to port state, configuration, LLDP MIB structures, deletion), the switch will set a change flag within the MIB for convenient notification to SNMP-based management systems.

Viewing Remote Device Information

LLDP information collected from neighboring systems can be viewed in numerous ways:

- Using a centrally-connected LLDP analysis server
- Using an SNMP agent to examine the G8264CS MIB
- Using the G8264CS Browser-Based Interface (BBI)
- Using commands on the G8264CS

The following command displays remote LLDP information:

```
RS 8264CS(config)# show lldp remote-device [<index number>]
```

To view a summary of remote information, omit the *Index number* parameter. For example:

```
RS 8264CS(config)# show lldp remote-device
LLDP Remote Devices Information
Legend(possible values in DMAC column) :
NB - Nearest Bridge - 01-80-C2-00-00-0E
NnTB - Nearest non-TPMR Bridge - 01-80-C2-00-00-03
NCB - Nearest Customer Bridge - 01-80-C2-00-00-00
Total number of current entries: 2

LocalPort|Index|Remote Chassis ID |Remote Port|Remote System Name|DMAC
-----|-----|-----|-----|-----|-----
MGT | 1 | 00 00 00 00 11 00 | 5 | C12 | NB
20 | 2 | 74 99 75 1c 75 00 | 44 | C3+ | NB
```

To view detailed information for a remote device, specify the *Index number* as found in the summary. For example, in keeping with the sample summary, to list details for the first remote device (with an Index value of 1), use the following command:

```
RS 8264CS(config)# show lldp remote-device 1
Local Port Alias: 3
    Remote Device Index      : 1
    Remote Device TTL       : 99
    Remote Device RxChanges  : false
    Chassis Type            : Mac Address
    Chassis Id              : 00-18-b1-33-1d-00
    Port Type               : Locally Assigned
    Port Id                 : 23
    Port Description        : 7

    System Name             :
    System Description      : Lenovo Networking Operating
System RackSwitch G8264CS, Lenovo Networking OS: version 8.2.1, Boot
Image: version 8.2.1

    System Capabilities Supported : bridge, router
    System Capabilities Enabled  : bridge, router

    Remote Management Address:
        Subtype                : IPV4
        Address                 : 10.100.120.181
        Interface Subtype      : ifIndex
        Interface Number       : 128
        Object Identifier      :
```

Note: Received LLDP information can change very quickly. When using show commands, it is possible that flags for some expected events may be too short-lived to be observed in the output.

To view detailed information of all remote devices, use the following command:

```
RS 8264CS# show lldp remote-device detail

Local Port Alias: MGTA
  Remote Device Index      : 1
  Remote Device TTL       : 4678
  Remote Device RxChanges : false
  Chassis Type            : Mac Address
  Chassis Id              : 08-17-f4-a1-db-00
  Port Type               : Locally Assigned
  Port Id                 : 25
  Port Description        : MGTA

  System Name             :
  System Description      : Lenovo Networking Operating

  Object Identifier         :

Total entries displayed: 2
```

Time-to-Live for Received Information

Each remote device LLDP packet includes an expiration time. If the switch port does not receive an LLDP update from the remote device before the time-to-live clock expires, the switch will consider the remote information to be invalid, and will remove all associated information from the MIB.

Remote devices can also intentionally set their LLDP time-to-live to 0, indicating to the switch that the LLDP information is invalid and must be immediately removed.

LLDP Example Configuration

1. Turn LLDP on globally.

```
RS 8264CS(config)# lldp enable
```

2. Set the global LLDP timer features.

```
RS 8264CS(config)# lldp refresh-interval 30           (Transmit each 30 seconds)  
RS 8264CS(config)# lldp transmission-delay 2        (No more often than 2 sec.)  
RS 8264CS(config)# lldp holdtime-multiplier 4       (Remote hold 4 intervals)  
RS 8264CS(config)# lldp reinit-delay 2             (Wait 2 sec. after reinit.)  
RS 8264CS(config)# lldp trap-notification-interval 5 (Minimum 5 sec. between)
```

3. Set LLDP options for each port.

```
RS 8264CS(config)# interface port <n>              (Select a switch port)  
RS 8264CS(config-if)# lldp admin-status tx_rx      (Transmit and receive LLDP)  
RS 8264CS(config-if)# lldp trap-notification       (Enable SNMP trap notifications)  
RS 8264CS(config-if)# lldp tlv all                 (Transmit all optional information)  
RS 8264CS(config-if)# exit
```

4. Enable syslog reporting.

```
RS 8264CS(config)# logging log lldp
```

5. Verify the configuration settings:

```
RS 8264CS(config)# show lldp
```

6. View remote device information as needed.

```
RS 8264CS(config)# show lldp remote-device  
or  
RS 8264CS(config)# show lldp remote-device <index number>  
or  
RS 8264CS(config)# show lldp remote-devices detail
```

Chapter 34. Simple Network Management Protocol

Lenovo Networking OS provides Simple Network Management Protocol (SNMP) version 1, version 2, and version 3 support for access through any network management software, such as IBM Director or HP-OpenView.

Note: SNMP read and write functions are enabled by default. For best security practices, if SNMP is not needed for your network, it is recommended that you disable these functions prior to connecting the switch to the network.

SNMP Version 1 & Version 2

To access the SNMP agent on the G8264CS, the read and write community strings on the SNMP manager must be configured to match those on the switch. The default read community string on the switch is `public` and the default write community string is `private`.

The read and write community strings on the switch can be changed using the following commands on the CLI:

```
RS 8264CS(config)# snmp-server read-community <1-32 characters>
-and-
RS 8264CS(config)# snmp-server write-community <1-32 characters>
```

The SNMP manager must be able to reach the management interface or any one of the IP interfaces on the switch.

For the SNMP manager to receive the SNMPv1 traps sent out by the SNMP agent on the switch, configure the trap host on the switch with the following command:

```
RS 8264CS(config)# snmp-server trap-source <trap source IP interface>
RS 8264CS(config)# snmp-server host <IPv4 address> <trap host community string>
```

Note: You can use a loopback interface to set the source IP address for SNMP traps. Use the following command to apply a configured loopback interface:

```
RS 8264CS(config)# snmp-server trap-source loopback <1-5>
```

SNMP Version 3

SNMP version 3 (SNMPv3) is an enhanced version of the Simple Network Management Protocol, approved by the Internet Engineering Steering Group in March, 2002. SNMPv3 contains additional security and authentication features that provide data origin authentication, data integrity checks, timeliness indicators and encryption to protect against threats such as masquerade, modification of information, message stream modification and disclosure.

SNMPv3 allows clients to query the MIBs securely.

SNMPv3 configuration is managed using the following command path menu:

```
RS 8264CS(config)# snmp-server ?
```

For more information on SNMP MIBs and the commands used to configure SNMP on the switch, see the *Lenovo Networking OS 8.2 Command Reference*.

Default Configuration

Lenovo N/OS has three SNMPv3 users by default. All the three users have access to all the MIBs supported by the switch:

- User 1 name is `adminmd5` (password `adminmd5`). Authentication used is MD5. Privacy protocol used is DES.
- User 2 name is `adminsha` (password `adminsha`). Authentication used is SHA. Privacy protocol used is DES.
- User 3 name is `adminshaaes` (password `Edpq132x!#9Zpx432w`). Authentication used is SHA. Privacy protocol used is AES-128.

In boot strict mode (See [“Boot Strict Mode” on page 44](#)), Lenovo N/OS has one SNMPv3 user:

- User 1 name is `adminshaaes` (password `Edpq132x!#9Zpx432w`). Authentication used is SHA. Privacy protocol used is AES-128.

Up to 17 SNMP users can be configured on the switch. To modify an SNMP user, enter the following commands:

```
RS 8264CS(config)# snmp-server user <1-17> name <1-32 characters>
```

Users can be configured to use the authentication/privacy options. The G8264CS support two authentication algorithms: MD5 and SHA, as specified in the following command:

```
RS 8264CS(config)# snmp-server user <1-17> authentication-protocol  
{md5|sha} authentication-password  
-or-  
RS 8264CS(config)# snmp-server user <1-17> authentication-protocol none
```

User Configuration Example

1. To configure a user with name “admin,” authentication type MD5, and authentication password of “admin,” privacy option DES with privacy password of “admin,” use the following CLI commands.

```
RS 8264CS(config)# snmp-server user 5 name admin
RS 8264CS(config)# snmp-server user 5 authentication-protocol md5
authentication-password
Changing authentication password; validation required:
Enter current admin password:          <admin. password>
Enter new authentication password:
                                         <auth. password; Should be more than 18 characters >
Re-enter new authentication password: <auth. password>
New authentication password accepted.

RS 8264CS(config)# snmp-server user 5 privacy-protocol des
privacy-password
Changing privacy password; validation required:
Enter current admin password:          <admin. password>
Enter new privacy password:
                                         <privacy password; Should be more than 18 characters>
Re-enter new privacy password:        <privacy password>
New privacy password accepted.
```

2. Configure a user access group, along with the views the group may access. Use the access table to configure the group’s access level.

```
RS 8264CS(config)# snmp-server access 5 name admingrp
RS 8264CS(config)# snmp-server access 5 level authpriv
RS 8264CS(config)# snmp-server access 5 read-view iso
RS 8264CS(config)# snmp-server access 5 write-view iso
RS 8264CS(config)# snmp-server access 5 notify-view iso
```

Because the read view, write view, and notify view are all set to “iso,” the user type has access to all private and public MIBs.

3. Assign the user to the user group. Use the group table to link the user to a particular access group.

```
RS 8264CS(config)# snmp-server group 5 user-name admin
RS 8264CS(config)# snmp-server group 5 group-name admingrp
```

If you want to allow user access only to certain MIBs, see “View-Based Configuration,” next.

View-Based Configurations

- Switch User equivalent

To configure an SNMP user equivalent to the switch “user” login, use the following configuration:

```
RS 8264CS(config)# snmp-server user 4 name usr
RS 8264CS(config)# snmp-server access 3 name usrgrp
RS 8264CS(config)# snmp-server access 3 read-view usr
RS 8264CS(config)# snmp-server access 3 write-view usr
RS 8264CS(config)# snmp-server access 3 notify-view usr
RS 8264CS(config)# snmp-server group 3 user-name usr
RS 8264CS(config)# snmp-server group 3 group-name usrgrp
RS 8264CS(config)# snmp-server view 6 name usr
RS 8264CS(config)# snmp-server view 6 tree 1.3.6.1.4.1.1872.2.5.1.2
RS 8264CS(config)# snmp-server view 7 name usr
RS 8264CS(config)# snmp-server view 7 tree 1.3.6.1.4.1.1872.2.5.1.3
RS 8264CS(config)# snmp-server view 8 name usr
RS 8264CS(config)# snmp-server view 8 tree 1.3.6.1.4.1.1872.2.5.2.2
RS 8264CS(config)# snmp-server view 9 name usr
RS 8264CS(config)# snmp-server view 9 tree 1.3.6.1.4.1.1872.2.5.2.3
RS 8264CS(config)# snmp-server view 10 name usr
RS 8264CS(config)# snmp-server view 10 tree 1.3.6.1.4.1.1872.2.5.2.3
RS 8264CS(config)# snmp-server view 11 name usr
RS 8264CS(config)# snmp-server view 11 tree 1.3.6.1.4.1.1872.2.5.3.3
```

- Switch Oper equivalent

```

RS 8264CS(config)# snmp-server user 5 name usr
                                     (Configure the user)
RS 8264CS(config)# snmp-server access 4 name opergrp
                                     (Configure access group 3)
RS 8264CS(config)# snmp-server access 4 read-view oper
RS 8264CS(config)# snmp-server access 4 write-view oper
RS 8264CS(config)# snmp-server access 4 notify-view oper
                                     (Assign oper to access group 4)
RS 8264CS(config)# snmp-server group 4 user-name oper
RS 8264CS(config)# snmp-server group 4 group-name opergrp
                                     (Create views for oper)
RS 8264CS(config)# snmp-server view 20 name oper
RS 8264CS(config)# snmp-server view 20 tree 1.3.6.1.4.1.1872.2.5.1.2
                                     (Agent information)
RS 8264CS(config)# snmp-server view 21 name oper
RS 8264CS(config)# snmp-server view 21 tree 1.3.6.1.4.1.1872.2.5.1.3
                                     (L2 statistics)
RS 8264CS(config)# snmp-server view 22 name oper
RS 8264CS(config)# snmp-server view 22 tree 1.3.6.1.4.1.1872.2.5.2.2
                                     (L2 information)
RS 8264CS(config)# snmp-server view 23 name oper
RS 8264CS(config)# snmp-server view 23 tree 1.3.6.1.4.1.1872.2.5.2.3
                                     (L3 statistics)
RS 8264CS(config)# snmp-server view 24 name oper
RS 8264CS(config)# snmp-server view 24 tree 1.3.6.1.4.1.1872.2.5.2.3
                                     (L3 information)

```

Secure Audit Logging

Flex System managers may use the authentication and encryption protocols of SNMPv3 to securely audit the switch. The audit logs record activity and severity for the overall system, user, and application processes. These logs can be used to trace a user's actions, monitor switch alerts, and confirm intrusion detection.

Networking OS uses SNMPv3 authorization to forward the logs securely to the management tool via the chassis management module (CMM). The switch supports both retrieving the logs via SNMP 'Get' requests and the forwarding of event logs via SNMP traps. Supported management tools are xHMC and other (security and information event management) SIEM tools like Qradar.

Security audit logging refers to the following event types:

- NTP Server/DHCP server configuration changes
- Switch management IP address changes
- OSPF/BGP/RIP authentication changes
- Software Resource alert :ARP Table/IP table/Route table/OSPF table full
- L3 Link down/up

Note: Audit logging is enabled by default and cannot be disabled. The audit logs are accessed remotely via SNMPv3 hosts.

Use the following commands to locally manage the logs:

RS 8264CS(config)# show sal reverse	<i>(Display most recent logs first)</i>
RS 8264CS(config)# clear sal	<i>(Clear audit logs)</i>

Configuring SNMP Trap Hosts

Follow these directions to configure SNMP trap hosts.

SNMPv1 Trap Host

1. Configure a user with no authentication and password.

```
RS 8264CS(config)# snmp-server user 10 name v1trap
```

2. Configure an access group and group table entries for the user. Use the following menu to specify which traps can be received by the user:

```
RS 8264CS(config)# snmp-server access <user number>
```

In the following example the user will receive the traps sent by the switch.

```
RS 8264CS(config)# snmp-server access 10      (Access group to view SNMPv1 traps)
    name v1trap
    security snmpv1
    notify-view iso
RS 8264CS(config)# snmp-server group 10      (Assign user to the access group)
    security snmpv1
    user-name v1trap
    group-name v1trap
```

3. Configure an entry in the notify table.

```
RS 8264CS(config)# snmp-server notify 10 name v1trap
RS 8264CS(config)# snmp-server notify 10 tag v1trap
```

4. Specify the IPv4 address and other trap parameters in the targetAddr and targetParam tables. Use the following commands to specify the user name associated with the targetParam table:

```
RS 8264CS(config)# snmp-server target-address 10 name v1trap address
    10.70.70.190
RS 8264CS(config)# snmp-server target-address 10 parameters-name v1param
RS 8264CS(config)# snmp-server target-address 10 taglist v1param
RS 8264CS(config)# snmp-server target-parameters 10 name v1param
RS 8264CS(config)# snmp-server target-parameters 10 user-name v1trap
RS 8264CS(config)# snmp-server target-parameters 10 message snmpv1
```

Note: N/OS 8.2 supports only IPv4 addresses for SNMPv1 and SNMPv2 trap hosts.

5. Use the community table to specify which community string is used in the trap.

```
RS 8264CS(config)# snmp-server community 10 (Define the community string)
    index v1trap
    name public
    user-name v1trap
```

SNMPv2 Trap Host Configuration

The SNMPv2 trap host configuration is similar to the SNMPv1 trap host configuration. Wherever you specify the model, use `snmpv2` instead of `snmpv1`.

```
RS 8264CS(config)# snmp-server user 10 name v2trap

RS 8264CS(config)# snmp-server group 10 security snmpv2
RS 8264CS(config)# snmp-server group 10 user-name v2trap
RS 8264CS(config)# snmp-server group 10 group-name v2trap
RS 8264CS(config)# snmp-server access 10 name v2trap
RS 8264CS(config)# snmp-server access 10 security snmpv2
RS 8264CS(config)# snmp-server access 10 notify-view iso

RS 8264CS(config)# snmp-server notify 10 name v2trap
RS 8264CS(config)# snmp-server notify 10 tag v2trap

RS 8264CS(config)# snmp-server target-address 10 name v2trap
address 100.10.2.1
RS 8264CS(config)# snmp-server target-address 10 taglist v2trap
RS 8264CS(config)# snmp-server target-address 10 parameters-name
v2param
RS 8264CS(config)# snmp-server target-parameters 10 name v2param
RS 8264CS(config)# snmp-server target-parameters 10 message snmpv2c
RS 8264CS(config)# snmp-server target-parameters 10 user-name v2trap
RS 8264CS(config)# snmp-server target-parameters 10 security snmpv2

RS 8264CS(config)# snmp-server community 10 index v2trap
RS 8264CS(config)# snmp-server community 10 user-name v2trap
```

Note: N/OS 8.2 supports only IPv4 addresses for SNMPv1 and SNMPv2 trap hosts.

SNMPv3 Trap Host Configuration

To configure a user for SNMPv3 traps, you can choose to send the traps with both privacy and authentication, with authentication only, or without privacy or authentication.

This is configured in the access table using the following commands:

```
RS 8264CS(config)# snmp-server access <1-32> level  
RS 8264CS(config)# snmp-server target-parameters <1-16> level
```

Configure the user in the user table accordingly.

It is not necessary to configure the community table for SNMPv3 traps because the community string is not used by SNMPv3.

The following example shows how to configure an SNMPv3 user v3trap with authentication only:

```
RS 8264CS(config)# snmp-server user 11 name v3trap  
RS 8264CS(config)# snmp-server user 11 authentication-protocol md5  
authentication-password  
Changing authentication password; validation required:  
Enter current admin password: <admin. password>  
Enter new authentication password: <auth. password>  
Re-enter new authentication password: <auth. password>  
New authentication password accepted.  
RS 8264CS(config)# snmp-server access 11 notify-view iso  
RS 8264CS(config)# snmp-server access 11 level authNopriv  
RS 8264CS(config)# snmp-server access 11 name v3trap  
RS 8264CS(config)# snmp-server group 11 user-name v3trap  
RS 8264CS(config)# snmp-server group 11 group-name v3trap  
RS 8264CS(config)# snmp-server notify 11 name v3trap  
RS 8264CS(config)# snmp-server notify 11 tag v3trap  
RS 8264CS(config)# snmp-server target-address 11 name v3trap address  
47.81.25.66  
RS 8264CS(config)# snmp-server target-address 11 taglist v3trap  
RS 8264CS(config)# snmp-server target-address 11 parameters-name v3param  
RS 8264CS(config)# snmp-server target-parameters 11 name v3param  
RS 8264CS(config)# snmp-server target-parameters 11 user-name v3trap  
RS 8264CS(config)# snmp-server target-parameters 11 level authNoPriv
```

SNMP MIBs

The N/OS SNMP agent supports SNMP version 3. Security is provided through SNMP community strings. The default community strings are “public” for SNMP GET operation and “private” for SNMP SET operation. The community string can be modified only through the Command Line Interface (CLI). Detailed SNMP MIBs and trap definitions of the N/OS SNMP agent are contained in the N/OS enterprise MIB document.

The N/OS SNMP agent supports the following standard MIBs:

- dot1x.mib
- ieee8021ab.mib
- ieee8023ad.mib
- rfc1213.mib
- rfc1215.mib
- rfc1493.mib
- rfc1573.mib
- rfc1643.mib
- rfc1657.mib
- rfc2189.mib
- rfc1850.mib
- rfc1907.mib
- rfc2037.mib
- rfc2233.mib
- rfc2465.mib
- rfc2571.mib
- rfc2572.mib
- rfc2573.mib
- rfc2574.mib
- rfc2575.mib
- rfc2576.mib
- rfc2790.mib
- rfc3176.mib

The following Fibre Channel/FCoE MIBs are supported:

- ibm-nos-fc-fcoe.mib
- fc_fe_exp.mib
- fcmgmt.mib

The N/OS SNMP agent supports the following generic traps as defined in RFC 1215:

- ColdStart
- WarmStart
- LinkDown
- LinkUp
- AuthenticationFailure

The SNMP agent also supports two Spanning Tree traps as defined in RFC 1493:

- NewRoot
- TopologyChange

The following are the enterprise SNMP traps supported in N/OS:

Table 38. *Lenovo N/OS-Supported Enterprise SNMP Traps*

Trap Name	Description
swLoginFailure	Signifies that someone failed to enter a valid username/password combination. swTrapDisplayString specifies whether the login attempt was from CONSOLE or TELNET. In case of TELNET login it also specifies the IP address of the host from which the attempt was made.
swValidLogin	Signifies that a user login has occurred.
swApplyComplete	Signifies that new configuration has been applied.
swSaveComplete	Signifies that new configuration has been saved.
swFwDownloadSucess	Signifies that firmware has been downloaded to [image1 image2 boot image].
swFwDownloadFailure	Signifies that firmware downloaded failed to [image1 image2 boot image].
swValidLogout	Signifies that a user logout has occurred.
swPrimaryPowerSupplyFailure	Signifies that the primary power supply has failed.
swPrimaryPowerSupplyFixed	Signifies that the primary power supply has been restored.
swDefAdminDisable	Signifies that the default admin account has been disabled.
swAcntStrngPswdNotMet	Signifies that the configured password does not match strong password complexity.
swAcntLocked	Signifies that account has been locked.
swAcntUnlocked	Signifies that account has been unlocked.

Table 38. *Lenovo N/OS-Supported Enterprise SNMP Traps (continued)*

Trap Name	Description
swStgNewRoot	Signifies that the bridge has become the new root of the STG.
swCistNewRoot	Signifies that the bridge has become the new root of the CIST.
swStgTopologyChanged	Signifies that there was a STG topology change.
swCistTopologyChanged	Signifies that there was a CIST topology change.
swHotlinksMasterUp	Signifies that the Master interface is active.
swHotlinksMasterDn	Signifies that the Master interface is not active.
swHotlinksBackupUp	Signifies that the Backup interface is active.
swHotlinksBackupDn	Signifies that the Backup interface is not active.
swHotlinksNone	Signifies that there are no active interfaces.
swTeamingCtrlUp	Signifies that the teaming is up.
swTeamingCtrlDown	Signifies that the teaming control is down.
swTeamingCtrlDownTearDownBlked	Signifies that the teaming control is down but teardown is blocked.
swTeamingCtrlError	Signifies error, action is undefined.
swLACPPortBlocked	Signifies that LACP is operationally down on a port, and traffic is blocked on the port.
swLACPPortUnblocked	Signifies that LACP is operationally up on a port, and traffic is no longer blocked on the port.
swLFDPortErrdisabled	Signifies that a port is error-disabled due to excessive link flaps.
swVlagInstanceUp	Signifies that VLAG instance is up identified in the trap message.
swVlagInstanceRemoteUp	Signifies that VLAG is down but instance on the remote instance is up.

Table 38. *Lenovo N/OS-Supported Enterprise SNMP Traps (continued)*

Trap Name	Description
swVlagInstanceLocalUp	Signifies that VLAG is down but local instance is up.
swVlagInstanceDown	Signifies that VLAG instance is down identified in the trap message.
swVlagIslUp	Signifies that connection between VLAG switches is up.
swVlagIslDown	Signifies that connection between VLAG switches is down.
sw8021x	Signifies 802.1x feature is enabled.
swDefGwUp	Signifies that the default gateway is alive. ipCurCfgGwIndex is the index of the Gateway in ipCurCfgGwTable. The range for ipCurCfgGwIndex is from 1 to ipGatewayTableMax. ipCurCfgGwAddr is the IP address of the default gateway.
swDefGwDown	Signifies that the default gateway is down. ipCurCfgGwIndex is the index of the Gateway in ipCurCfgGwTable. The range for ipCurCfgGwIndex is from 1 to ipGatewayTableMax. ipCurCfgGwAddr is the IP address of the default gateway.
swDefGwInService	Signifies that the default gateway is up and in service. ipCurCfgGwIndex is the index of the Gateway in ipCurCfgGwTable. The range for ipCurCfgGwIndex is from 1 to ipGatewayTableMax. ipCurCfgGwAddr is the IP address of the default gateway.
swDefGwNotInService	Signifies that the default gateway is alive but not in service. ipCurCfgGwIndex is the index of the Gateway in ipCurCfgGwTable. The range for ipCurCfgGwIndex is from 1 to ipGatewayTableMax. ipCurCfgGwAddr is the IP address of the default gateway.

Table 38. *Lenovo N/OS-Supported Enterprise SNMP Traps (continued)*

Trap Name	Description
swVrrpNewMaster	Indicates that the sending agent has transitioned to “Master” state. vrrpCurCfgVirtRtrIndx is the VRRP virtual router table index referenced in vrrpCurCfgVirtRtrTable. The range is from 1 to vrrpVirtRtrTableMaxSize. vrrpCurCfgVirtRtrAddr is the VRRP virtual router IP address.
swVrrpNewBackup	Indicates that the sending agent has transitioned to “Backup” state. vrrpCurCfgVirtRtrIndx is the VRRP virtual router table index referenced in vrrpCurCfgVirtRtrTable. The range is from 1 to vrrpVirtRtrTableMaxSize. vrrpCurCfgVirtRtrAddr is the VRRP virtual router IP address.
swVrrpAuthFailure	Signifies that a packet has been received from a router whose authentication key or authentication type conflicts with this router's authentication key or authentication type. vrrpCurCfgIfIndx is the VRRP interface index. This is equivalent to ifIndex in RFC 1213 mib. The range is from 1 to vrrpIfTableMaxSize. vrrpCurCfgIfPasswd is the password for authentication. It is a DisplayString of 0 to 7 characters.
swTcpHoldDown	Signifies that new TCP connection requests from a particular client will be blocked for a pre-determined amount of time since the rate of new TCP connections from that client has reached a pre-determined threshold. The fltCurCfgSrcIp is the client source IP address for which new TCP connection requests will be blocked. The swTrapRate specifies the amount of time in minutes that the particular client will be blocked.

Table 38. *Lenovo N/OS-Supported Enterprise SNMP Traps (continued)*

Trap Name	Description
swNTPSyncFailed	Signifies that synchronization with the NTP server has failed.
swNTPUpdateClock	Signifies that the system clock is updated with NTP server.
swECMPGatewayUp	Signifies that the ECMP gateway is up.
swECMPGatewayDown	Signifies that the ECMP gateway is down.
swTempExceedThreshold	Signifies that the switch temperature has exceeded maximum safety limits.
swFanFailure	Signifies that the fan failure has been detected.
swFanFailureFixed	Signifies that the fan failure has been fixed.
swTempReturnThreshold	Signifies that the switch temperature has returned to under maximum safety limits.
swVMGroupVMotion	Signifies that a virtual machine has moved from a port to another.
swVMGroupVMOnline	Signifies that an advance provisioned virtual machine has come online.
swVMGroupVMVlanChange	Signifies that a virtual machine has entered a VLAN, or changed the VLAN.
swVmCheckSpoofedvm	Signifies that a spoofed VM MAC was found.

Switch Images and Configuration Files

This section describes how to use MIB calls to work with switch images and configuration files. You can use a standard SNMP tool to perform the actions, using the MIBs listed in [Table 39](#).

[Table 39](#) lists the MIBs used to perform operations associated with the Switch Image and Configuration files.

Table 39. *MIBs for Switch Image and Configuration Files*

MIB Name	MIB OID
agTransferServer	1.3.6.1.4.1872.2.5.1.1.7.1.0
agTransferImage	1.3.6.1.4.1872.2.5.1.1.7.2.0
agTransferImageFileName	1.3.6.1.4.1872.2.5.1.1.7.3.0
agTransferCfgFileName	1.3.6.1.4.1872.2.5.1.1.7.4.0
agTransferDumpFileName	1.3.6.1.4.1872.2.5.1.1.7.5.0
agTransferAction	1.3.6.1.4.1872.2.5.1.1.7.6.0
agTransferLastActionStatus	1.3.6.1.4.1872.2.5.1.1.7.7.0
agTransferUserName	1.3.6.1.4.1872.2.5.1.1.7.9.0
agTransferPassword	1.3.6.1.4.1.1872.2.5.1.1.7.10.0
agTransferTSDumpFileName	1.3.6.1.4.1.1872.2.5.1.1.7.11.0

The following SNMP actions can be performed using the MIBs listed in [Table 39](#).

- Load a new Switch image (boot or running) from a FTP/TFTP server
- Load a previously saved switch configuration from a FTP/TFTP server
- Save the switch configuration to a FTP/TFTP server
- Save a switch dump to a FTP/TFTP server

Loading a New Switch Image

To load a new switch image with the name "MyNewImage-1.img" into image2, follow these steps. This example shows an FTP/TFTP server with the IPv4 address 192.168.10.10, though IPv6 is also supported.

1. Set the FTP/TFTP server address where the switch image resides:

```
Set agTransferServer.0 "192.168.10.10"
```

2. Set the area where the new image will be loaded:

```
Set agTransferImage.0 "image2"
```

3. Set the name of the image:

```
Set agTransferImageFileName.0 "MyNewImage-1.img"
```

4. If you are using an FTP server, enter a username:

```
Set agTransferUserName.0 "MyName"
```

5. If you are using an FTP server, enter a password:

```
Set agTransferPassword.0 "MyPassword"
```

6. Initiate the transfer. To transfer a switch image, enter 2 (gting):

```
Set agTransferAction.0 "2"
```

Loading a Saved Switch Configuration

To load a saved switch configuration with the name "MyRunningConfig.cfg" into the switch, follow these steps. This example shows a TFTP server at IPv4 address 192.168.10.10, though IPv6 is also supported.

1. Set the FTP/TFTP server address where the switch configuration file resides:

```
Set agTransferServer.0 "192.168.10.10"
```

2. Set the name of the configuration file:

```
Set agTransferCfgFileName.0 "MyRunningConfig.cfg"
```

3. If you are using an FTP server, enter a username:

```
Set agTransferUserName.0 "MyName"
```

4. If you are using an FTP server, enter a password:

```
Set agTransferPassword.0 "MyPassword"
```

5. Initiate the transfer. To restore a running configuration, enter 3:

```
Set agTransferAction.0 "3"
```

Saving the Switch Configuration

To save the switch configuration to a FTP/TFTP server follow these steps. This example shows a FTP/TFTP server with the IPv4 address 192.168.10.10, though IPv6 is also supported.

1. Set the FTP/TFTP server address where the configuration file is saved:

```
Set agTransferServer.0 "192.168.10.10"
```

2. Set the name of the configuration file:

```
Set agTransferCfgFileName.0 "MyRunningConfig.cfg"
```

3. If you are using an FTP server, enter a username:

```
Set agTransferUserName.0 "MyName"
```

4. If you are using an FTP server, enter a password:

```
Set agTransferPassword.0 "MyPassword"
```

5. Initiate the transfer. To save a running configuration file, enter 4:

```
Set agTransferAction.0 "4"
```

Saving a Switch Dump

To save a switch dump to a FTP/TFTP server, follow these steps. This example shows an FTP/TFTP server with the 192.168.10.10, though IPv6 is also supported.

1. Set the FTP/TFTP server address where the dump file will be saved:

```
Set agTransferServer.0 "192.168.10.10"
```

2. Set the name of the dump file:

```
Set agTransferDumpFileName.0 "MyDumpFile.dmp"
```

3. If you are using an FTP server, enter a username:

```
Set agTransferUserName.0 "MyName"
```

4. If you are using an FTP server, enter a password:

```
Set agTransferPassword.0 "MyPassword"
```

5. Initiate the transfer. To save a dump file, enter 5:

```
Set agTransferAction.0 "5"
```

Part 8: Monitoring

The ability to monitor traffic passing through the G8264CS can be invaluable for troubleshooting some types of networking problems. This sections cover the following monitoring features:

- Remote Monitoring (RMON)
- sFlow
- Port Mirroring

Chapter 35. Remote Monitoring

Remote Monitoring (RMON) allows network devices to exchange network monitoring data.

RMON allows the switch to perform the following functions:

- Track events and trigger alarms when a threshold is reached.
- Notify administrators by issuing a syslog message or SNMP trap.

RMON Overview

The RMON MIB provides an interface between the RMON agent on the switch and an RMON management application. The RMON MIB is described in RFC 2189.

The RMON standard defines objects that are suitable for the management of Ethernet networks. The RMON agent continuously collects statistics and proactively monitors switch performance. RMON allows you to monitor traffic flowing through the switch.

The switch supports the following RMON Groups, as described in RFC 2189:

- Group 1: Statistics
- Group 2: History
- Group 3: Alarms
- Group 9: Events

RMON Group 1—Statistics

The switch supports collection of Ethernet statistics as outlined in the RMON statistics MIB, in reference to etherStatsTable. You can configure RMON statistics on a per-port basis.

RMON statistics are sampled every second, and new data overwrites any old data on a given port.

Note: RMON port statistics must be enabled for the port before you can view RMON statistics.

Example Configuration

1. Enable RMON on a port.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# rmon
```

2. View RMON statistics for the port.

```
RS 8264CS(config-if)# show interface port 1 rmon-counters
```

```
-----
RMON statistics for port 1:
etherStatsDropEvents:                NA
etherStatsOctets:                    7305626
etherStatsPkts:                      48686
etherStatsBroadcastPkts:             4380
etherStatsMulticastPkts:             6612
etherStatsCRCAlignErrors:            22
etherStatsUndersizePkts:              0
etherStatsOversizePkts:              0
etherStatsFragments:                 2
etherStatsJabbers:                   0
etherStatsCollisions:                0
etherStatsPkts64octets:               27445
etherStatsPkts65to127octets:         12253
etherStatsPkts128to255octets:        1046
etherStatsPkts256to511octets:         619
etherStatsPkts512to1023octets:       7283
etherStatsPkts1024to1518octets:      38
```

RMON Group 2—History

The RMON History Group allows you to sample and archive Ethernet statistics for a specific interface during a specific time interval. History sampling is done per port.

Note: RMON port statistics must be enabled for the port before an RMON History Group can monitor the port.

Data is stored in *buckets*, which store data gathered during discreet sampling intervals. At each configured interval, the History index takes a sample of the current Ethernet statistics, and places them into a bucket. History data buckets reside in dynamic memory. When the switch is re-booted, the buckets are emptied.

Requested buckets are the number of buckets, or data slots, requested by the user for each History Group. Granted buckets are the number of buckets granted by the system, based on the amount of system memory available. The system grants a maximum of 50 buckets.

You can use an SNMP browser to view History samples.

History MIB Object ID

The type of data that can be sampled must be of an `ifIndex` object type, as described in RFC 1213 and RFC 1573. The most common data type for the History sample is as follows:

1.3.6.1.2.1.2.2.1.1.<x>

The last digit (*x*) represents the number of the port to monitor.

Configuring RMON History

Perform the following steps to configure RMON History on a port.

1. Enable RMON on a port.

```
RS 8264CS(config)# interface port 1
RS 8264CS(config-if)# rmon
RS 8264CS(config-if)# exit
```

2. Configure the RMON History parameters for a port.

```
RS 8264CS(config)# rmon history 1 interface-oid 1.3.6.1.2.1.2.2.1.1.<x>
RS 8264CS(config)# rmon history 1 requested-buckets 30
RS 8264CS(config)# rmon history 1 polling-interval 120
RS 8264CS(config)# rmon history 1 owner "rmon port 1 history"
```

where <x> is the number of the port to monitor. For example, the full OID for port 1 would be:

1.3.6.1.2.1.2.2.1.1.129

3. View RMON history for the port.

```
RS 8264CS(config)# show rmon history
RMON History group configuration:

Index          IFOID          Interval    Rbnum    Gbnum
-----
  1  1.3.6.1.2.1.2.2.1.1.129    120      30      30

Index          Owner
-----
  1  rmon port 1 history
```

RMON Group 3—Alarms

The RMON Alarm Group allows you to define a set of thresholds used to determine network performance. When a configured threshold is crossed, an alarm is generated. For example, you can configure the switch to issue an alarm if more than 1,000 CRC errors occur during a 10-minute time interval.

Each Alarm index consists of a variable to monitor, a sampling time interval, and parameters for rising and falling thresholds. The Alarm Group can be used to track rising or falling values for a MIB object. The object must be a counter, gauge, integer, or time interval.

Use one of the following commands to correlate an Alarm index to an Event index:

```
RS 8264CS(config)# rmon alarm <alarm number> rising-crossing-index
                    <event number>
RS 8264CS(config)# rmon alarm <alarm number> falling-crossing-index
                    <event number>
```

When the alarm threshold is reached, the corresponding event is triggered.

Alarm MIB objects

The most common data types used for alarm monitoring are ifStats: errors, drops, bad CRCs, and so on. These MIB Object Identifiers (OIDs) correlate to the ones tracked by the History Group. An example statistic follows:

```
1.3.6.1.2.1.2.2.1.1.129 - mgmt.icmp.icmpInMsgs
```

This value represents the alarm's MIB OID, as a string. Note that for non-tables, you must supply a .0 to specify end node.

Configuring RMON Alarms

Configure the RMON Alarm parameters to track ICMP messages.

```
RS 8264CS(config)# rmon alarm 1 oid 1.3.6.1.2.1.5.8.0
RS 8264CS(config)# rmon alarm 1 alarm-type rising
RS 8264CS(config)# rmon alarm 1 rising-crossing-index 110
RS 8264CS(config)# rmon alarm 1 interval 60
RS 8264CS(config)# rmon alarm 1 rising-limit 200
RS 8264CS(config)# rmon alarm 1 sample delta
RS 8264CS(config)# rmon alarm 1 owner "Alarm for icmpInEchos"
```

This configuration creates an RMON alarm that checks `icmpInEchos` on the switch once every minute. If the statistic exceeds 200 within a 60 second interval, an alarm is generated that triggers event index 110.

RMON Group 9—Events

The RMON Event Group allows you to define events that are triggered by alarms. An event can be a log message, an SNMP trap, or both.

When an alarm is generated, it triggers a corresponding event notification. Use the following commands to correlate an Event index to an alarm:

```
RS 8264CS(config)# rmon alarm <alarm number> rising-crossing-index
<event number>
RS 8264CS(config)# rmon alarm <alarm number> falling-crossing-index
<event number>
```

RMON events use SNMP and syslogs to send notifications. Therefore, an SNMP trap host must be configured for trap event notification to work properly.

RMON uses a syslog host to send syslog messages. Therefore, an existing syslog host must be configured for event log notification to work properly. Each log event generates a syslog of type RMON that corresponds to the event.

For example, to configure the RMON event parameters.

```
RS 8264CS(config)# rmon event 110 type log
RS 8264CS(config)# rmon event 110 description "SYSLOG_this_alarm"
RS 8264CS(config)# rmon event 110 owner "log icmpInEchos alarm"
```

This configuration creates an RMON event that sends a syslog message each time it is triggered by an alarm.

Chapter 36. sFlow

The G8264CS supports sFlow technology for monitoring traffic in data networks. The switch includes an embedded sFlow agent which can be configured to provide continuous monitoring information of IPv4 traffic to a central sFlow analyzer.

The switch is responsible only for forwarding sFlow information. A separate sFlow analyzer is required elsewhere on the network to interpret sFlow data.

Note: Lenovo Networking OS 8.2 does not support IPv6 for sFlow.

sFlow Statistical Counters

The G8264CS can be configured to send network statistics to an sFlow analyzer at regular intervals. For each port, a polling interval of 5 to 60 seconds can be configured, or 0 (the default) to disable this feature.

When polling is enabled, at the end of each configured polling interval, the G8264CS reports general port statistics and port Ethernet statistics.

sFlow Network Sampling

In addition to statistical counters, the G8264CS can be configured to collect periodic samples of the traffic data received on each port. For each sample, 128 bytes are copied, UDP-encapsulated, and sent to the configured sFlow analyzer.

For each port, the sFlow sampling rate can be configured to occur once each 256 to 65536 packets, or 0 to disable (the default). A sampling rate of 256 means that one sample will be taken for approximately every 256 packets received on the port. The sampling rate is statistical, however. It is possible to have slightly more or fewer samples sent to the analyzer for any specific group of packets (especially under low traffic conditions). The actual sample rate becomes most accurate over time, and under higher traffic flow.

sFlow sampling has the following restrictions:

- **Sample Rate**—The fastest sFlow sample rate is 1 out of every 256 packets.
- **ACLs**—sFlow sampling is performed before ACLs are processed. For ports configured both with sFlow sampling and one or more ACLs, sampling will occur regardless of the action of the ACL.
- **Port Mirroring**—sFlow sampling will not occur on mirrored traffic. If sFlow sampling is enabled on a port that is configured as a port monitor, the mirrored traffic will not be sampled.
- **Egress traffic**—sFlow sampling will not occur on egress traffic.

Note: Although sFlow sampling is not generally a CPU-intensive operation, configuring fast sampling rates (such as once every 256 packets) on ports under heavy traffic loads can cause switch CPU utilization to reach maximum. Use larger rate values for ports that experience heavy traffic.

sFlow Example Configuration

1. Specify the location of the sFlow analyzer (the server and optional port to which the sFlow information will be sent):

```
RS 8264CS(config)# sflow server <IPv4 address>(sFlow server address)
RS 8264CS(config)# sflow port <service port>(Set the optional service port)
RS 8264CS(config)# sflow enable (Enable sFlow features)
```

By default, the switch uses established sFlow service port 6343.

To disable sFlow features across all ports, use the `no sflow enable` command.

2. On a per-port basis, define the statistics polling rate:

```
RS 8264CS(config)# interface port <port>
RS 8264CS(config-if)# sflow polling <polling rate>(Statistics polling rate)
```

Specify a polling rate between 5 and 60 seconds, or 0 to disable. By default, polling is 0 (disabled) for each port.

3. On a per-port basis, define the data sampling rate:

```
RS 8264CS(config-if)# sflow sampling <sampling rate>(Data sampling rate)
```

Specify a sampling rate between 256 and 65536 packets, or 0 to disable. By default, the sampling rate is 0 (disabled) for each port.

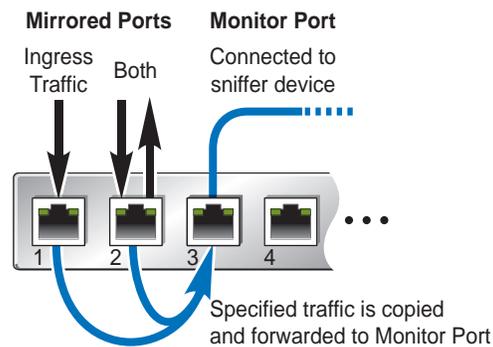

4. Save the configuration.

Chapter 37. Port Mirroring

The Lenovo Networking OS port mirroring feature allows you to mirror (copy) the packets of a target port, and forward them to a monitoring port. Port mirroring functions for all layer 2 and layer 3 traffic on a port. This feature can be used as a troubleshooting tool or to enhance the security of your network. For example, an IDS server or other traffic sniffer device or analyzer can be connected to the monitoring port to detect intruders attacking the network.

The G8264CS supports a “many to one” mirroring model. As shown in [Figure 55](#), selected traffic for ports 1 and 2 is being monitored by port 3. In the example, both ingress traffic and egress traffic on port 2 are copied and forwarded to the monitor. However, port 1 mirroring is configured so that only ingress traffic is copied and forwarded to the monitor. A device attached to port 3 can analyze the resulting mirrored traffic.

Figure 55. Mirroring Ports

The G8264CS supports four monitor ports. Each monitor port can receive mirrored traffic from any number of target ports.

Lenovo N/OS does not support “one to many” or “many to many” mirroring models where traffic from a specific port traffic is copied to multiple monitor ports. For example, port 1 traffic cannot be monitored by both port 3 and 4 at the same time, nor can port 2 ingress traffic be monitored by a different port than its egress traffic.

Ingress and egress traffic is duplicated and sent to the monitor port after processing.

Configuring Port Mirroring

The following procedure may be used to configure port mirroring for the example shown in [Figure 55 on page 521](#):

1. Specify the monitoring port, the mirroring port(s), and the port-mirror direction.

```
RS 8264CS(config)# port-mirroring monitor-port 3 mirroring-port 1 in
RS 8264CS(config)# port-mirroring monitor-port 3 mirroring-port 2 both
```

2. Enable port mirroring.

```
RS 8264CS(config)# port-mirroring enable
```

3. View the current configuration.

```
RS 8264CS# show port-mirroring

Port Monitoring : Enabled

Monitoring Ports      Mirrored Ports
3                     1, in
                     2, both
```

Part 9: Appendices

- Glossary
- Getting help and technical assistance
- Notices

Appendix A. Glossary

CNA	Converged Network Adapter. A device used for I/O consolidation such as that in Converged Enhanced Ethernet (CEE) environments implementing Fibre Channel over Ethernet (FCoE). The CNA performs the duties of both a Network Interface Card (NIC) for Local Area Networks (LANs) and a Host Bus Adapter (HBA) for Storage Area Networks (SANs).
DIP	The destination IP address of a frame.
Dport	The destination port (application socket: for example, http-80/https-443/DNS-53)
HBA	Host Bus Adapter. An adapter or card that interfaces with device drivers in the host operating system and the storage target in a Storage Area Network (SAN). It is equivalent to a Network Interface Controller (NIC) from a Local Area Network (LAN).
NAT	Network Address Translation. Any time an IP address is changed from one source IP or destination IP address to another address, network address translation can be said to have taken place. In general, half NAT is when the destination IP or source IP address is changed from one address to another. Full NAT is when both addresses are changed from one address to another. No NAT is when neither source nor destination IP addresses are translated.
Preemption	In VRRP, preemption will cause a Virtual Router that has a lower priority to go into backup if a peer Virtual Router starts advertising with a higher priority.
Priority	In VRRP, the value given to a Virtual Router to determine its ranking with its peer(s). Minimum value is 1 and maximum value is 254. Default is 100. A higher number will win out for master designation.
Proto (Protocol)	The protocol of a frame. Can be any value represented by a 8-bit value in the IP header adherent to the IP specification (for example, TCP, UDP, OSPF, ICMP, and so on.)
SIP	The source IP address of a frame.
SPort	The source port (application socket: for example, HTTP-80/HTTPS-443/DNS-53).
Tracking	<p>In VRRP, a method to increase the priority of a virtual router and thus master designation (with preemption enabled). Tracking can be very valuable in an active/active configuration.</p> <p>You can track the following:</p> <ul style="list-style-type: none">● Active IP interfaces on the Web switch (increments priority by 2 for each)● Active ports on the same VLAN (increments priority by 2 for each)● Number of virtual routers in master mode on the switch
VIR	Virtual Interface Router. A VRRP address is an IP interface address shared between two or more virtual routers.
Virtual Router	A shared address between two devices utilizing VRRP, as defined in RFC 2338. One virtual router is associated with an IP interface. This is one of the IP interfaces that the switch is assigned. All IP interfaces on the G8264CSs must be in a VLAN. If there is more than one VLAN defined on the Web switch, then the VRRP broadcasts will only be sent out on the VLAN of which the associated IP interface is a member.

VRID	<p>Virtual Router Identifier. In VRRP, a numeric ID is used by each virtual router to create its MAC address and identify its peer for which it is sharing this VRRP address. The VRRP MAC address as defined in the RFC is 00-00-5E-00-01-<i><VRID></i>.</p> <p>If you have a VRRP address that two switches are sharing, then the VRID number needs to be identical on both switches so each virtual router on each switch knows with whom to share.</p>
VRRP	<p>Virtual Router Redundancy Protocol. A protocol that acts very similarly to Cisco's proprietary HSRP address sharing protocol. The reason for both of these protocols is so devices have a next hop or default gateway that is always available. Two or more devices sharing an IP interface are either advertising or listening for advertisements. These advertisements are sent via a broadcast message to an address such as 224.0.0.18.</p> <p>With VRRP, one switch is considered the master and the other the backup. The master is always advertising via the broadcasts. The backup switch is always listening for the broadcasts. If the master stops advertising, the backup will take over ownership of the VRRP IP and MAC addresses as defined by the specification. The switch announces this change in ownership to the devices around it by way of a Gratuitous ARP, and advertisements. If the backup switch didn't do the Gratuitous ARP the Layer 2 devices attached to the switch would not know that the MAC address had moved in the network. For a more detailed description, refer to RFC 2338.</p>

Appendix B. Getting help and technical assistance

If you need help, service, or technical assistance or just want more information about Lenovo products, you will find a wide variety of sources available from Lenovo to assist you.

Use this information to obtain additional information about Lenovo and Lenovo products, and determine what to do if you experience a problem with your Lenovo system or optional device.

Note: This section includes references to IBM web sites and information about obtaining service. IBM is Lenovo's preferred service provider for the System x, Flex System, and NeXtScale System products.

Before you call, make sure that you have taken these steps to try to solve the problem yourself.

If you believe that you require warranty service for your Lenovo product, the service technicians will be able to assist you more efficiently if you prepare before you call.

- Check all cables to make sure that they are connected.
- Check the power switches to make sure that the system and any optional devices are turned on.
- Check for updated software, firmware, and operating-system device drivers for your Lenovo product. The Lenovo Warranty terms and conditions state that you, the owner of the Lenovo product, are responsible for maintaining and updating all software and firmware for the product (unless it is covered by an additional maintenance contract). Your service technician will request that you upgrade your software and firmware if the problem has a documented solution within a software upgrade.
- If you have installed new hardware or software in your environment, check the [IBM ServerProven website](#) to make sure that the hardware and software is supported by your product.
- Go to the [IBM Support portal](#) to check for information to help you solve the problem.
- Gather the following information to provide to the service technician. This data will help the service technician quickly provide a solution to your problem and ensure that you receive the level of service for which you might have contracted.
 - Hardware and Software Maintenance agreement contract numbers, if applicable
 - Machine type number (if applicable—Lenovo 4-digit machine identifier)
 - Model number
 - Serial number
 - Current system UEFI and firmware levels
 - Other pertinent information such as error messages and logs

- Start the process of determining a solution to your problem by making the pertinent information available to the service technicians. The IBM service technicians can start working on your solution as soon as you have completed and submitted an Electronic Service Request.

You can solve many problems without outside assistance by following the troubleshooting procedures that Lenovo provides in the online help or in the Lenovo product documentation. The Lenovo product documentation also describes the diagnostic tests that you can perform. The documentation for most systems, operating systems, and programs contains troubleshooting procedures and explanations of error messages and error codes. If you suspect a software problem, see the documentation for the operating system or program.

Appendix C. Notices

Lenovo may not offer the products, services, or features discussed in this document in all countries. Consult your local Lenovo representative for information on the products and services currently available in your area.

Any reference to a Lenovo product, program, or service is not intended to state or imply that only that Lenovo product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any Lenovo intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any other product, program, or service.

Lenovo may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

Lenovo (United States), Inc.
1009 Think Place - Building One
Morrisville, NC 27560
U.S.A.

Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. Lenovo may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

The products described in this document are not intended for use in implantation or other life support applications where malfunction may result in injury or death to persons. The information contained in this document does not affect or change Lenovo product specifications or warranties.

Nothing in this document shall operate as an express or implied license or indemnity under the intellectual property rights of Lenovo or third parties. All information contained in this document was obtained in specific environments and is presented as an illustration. The result obtained in other operating environments may vary.

Lenovo may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Any references in this publication to non-Lenovo Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this Lenovo product, and use of those Web sites is at your own risk.

Any performance data contained herein was determined in a controlled environment. Therefore, the result obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Trademarks

Lenovo, the Lenovo logo, Flex System, System x, NeXtScale System, and X-Architecture are trademarks of Lenovo in the United States, other countries, or both.

Intel and Intel Xeon are trademarks of Intel Corporation in the United States, other countries, or both.

Internet Explorer, Microsoft, and Windows are trademarks of the Microsoft group of companies.

Linux is a registered trademark of Linus Torvalds.

Other company, product, or service names may be trademarks or service marks of others.

Important Notes

Processor speed indicates the internal clock speed of the microprocessor; other factors also affect application performance.

CD or DVD drive speed is the variable read rate. Actual speeds vary and are often less than the possible maximum.

When referring to processor storage, real and virtual storage, or channel volume, KB stands for 1 024 bytes, MB stands for 1 048 576 bytes, and GB stands for 1 073 741 824 bytes.

When referring to hard disk drive capacity or communications volume, MB stands for 1 000 000 bytes, and GB stands for 1 000 000 000 bytes. Total user-accessible capacity can vary depending on operating environments.

Maximum internal hard disk drive capacities assume the replacement of any standard hard disk drives and population of all hard-disk-drive bays with the largest currently supported drives that are available from Lenovo.

Maximum memory might require replacement of the standard memory with an optional memory module.

Each solid-state memory cell has an intrinsic, finite number of write cycles that the cell can incur. Therefore, a solid-state device has a maximum number of write cycles that it can be subjected to, expressed as total bytes written (TBW). A device that has exceeded this limit might fail to respond to system-generated commands or might be incapable of being written to. Lenovo is not responsible for replacement of a device that has exceeded its maximum guaranteed number of program/erase cycles, as documented in the Official Published Specifications for the device.

Lenovo makes no representations or warranties with respect to non-Lenovo products. Support (if any) for the non-Lenovo products is provided by the third party, not Lenovo.

Some software might differ from its retail version (if available) and might not include user manuals or all program functionality.

Recycling Information

Lenovo encourages owners of information technology (IT) equipment to responsibly recycle their equipment when it is no longer needed. Lenovo offers a variety of programs and services to assist equipment owners in recycling their IT products. For information on recycling Lenovo products, go to:

<http://www.lenovo.com/recycling>

Particulate Contamination

Attention: Airborne particulates (including metal flakes or particles) and reactive gases acting alone or in combination with other environmental factors such as humidity or temperature might pose a risk to the device that is described in this document.

Risks that are posed by the presence of excessive particulate levels or concentrations of harmful gases include damage that might cause the device to malfunction or cease functioning altogether. This specification sets forth limits for particulates and gases that are intended to avoid such damage. The limits must not be viewed or used as definitive limits, because numerous other factors, such as temperature or moisture content of the air, can influence the impact of particulates or environmental corrosives and gaseous contaminant transfer. In the absence of specific limits that are set forth in this document, you must implement practices that maintain particulate and gas levels that are consistent with the protection of human health and safety. If Lenovo determines that the levels of particulates or gases in your environment have caused damage to the device, Lenovo may condition provision of repair or replacement of devices or parts on implementation of appropriate remedial measures to mitigate such environmental contamination. Implementation of such remedial measures is a customer responsibility..

Contaminant	Limits
Particulate	<ul style="list-style-type: none"> The room air must be continuously filtered with 40% atmospheric dust spot efficiency (MERV 9) according to ASHRAE Standard 52.2¹. Air that enters a data center must be filtered to 99.97% efficiency or greater, using high-efficiency particulate air (HEPA) filters that meet MIL-STD-282. The deliquescent relative humidity of the particulate contamination must be more than 60%². The room must be free of conductive contamination such as zinc whiskers.
Gaseous	<ul style="list-style-type: none"> Copper: Class G1 as per ANSI/ISA 71.04-1985³ Silver: Corrosion rate of less than 300 Å in 30 days

¹ ASHRAE 52.2-2008 - *Method of Testing General Ventilation Air-Cleaning Devices for Removal Efficiency by Particle Size*. Atlanta: American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc.

² The deliquescent relative humidity of particulate contamination is the relative humidity at which the dust absorbs enough water to become wet and promote ionic conduction.

³ ANSI/ISA-71.04-1985. *Environmental conditions for process measurement and control systems: Airborne contaminants*. Instrument Society of America, Research Triangle Park, North Carolina, U.S.A.

Telecommunication Regulatory Statement

This product may not be certified in your country for connection by any means whatsoever to interfaces of public telecommunications networks. Further certification may be required by law prior to making any such connection. Contact a Lenovo representative or reseller for any questions.

Electronic Emission Notices

When you attach a monitor to the equipment, you must use the designated monitor cable and any interference suppression devices that are supplied with the monitor.

Federal Communications Commission (FCC) Statement

Note: This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to Part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user will be required to correct the interference at his own expense.

Properly shielded and grounded cables and connectors must be used to meet FCC emission limits. Lenovo is not responsible for any radio or television interference caused by using other than recommended cables and connectors or by unauthorized changes or modifications to this equipment. Unauthorized changes or modifications could void the user's authority to operate the equipment.

This device complies with Part 15 of the FCC Rules. Operation is subject to the following two conditions: (1) this device may not cause harmful interference, and (2) this device must accept any interference received, including interference that might cause undesired operation.

Industry Canada Class A Emission Compliance Statement

This Class A digital apparatus complies with Canadian ICES-003.

Avis de Conformité à la Réglementation d'Industrie Canada

Cet appareil numérique de la classe A est conforme à la norme NMB-003 du Canada.

Australia and New Zealand Class A Statement

Attention: This is a Class A product. In a domestic environment this product may cause radio interference in which case the user may be required to take adequate measures.

European Union EMC Directive Conformance Statement

This product is in conformity with the protection requirements of EU Council Directive 2004/108/EC on the approximation of the laws of the Member States relating to electromagnetic compatibility. Lenovo cannot accept responsibility for any failure to satisfy the protection requirements resulting from a non-recommended modification of the product, including the installation of option cards from other manufacturers.

This product has been tested and found to comply with the limits for Class A Information Technology Equipment according to European Standard EN 55022. The limits for Class A equipment were derived for commercial and industrial environments to provide reasonable protection against interference with licensed communication equipment.

Lenovo, Einsteinova 21, 851 01 Bratislava, Slovakia

Germany Class A Statement

Zulassungsbescheinigung laut dem Deutschen Gesetz über die elektromagnetische Verträglichkeit von Betriebsmitteln, EMVG vom 20. Juli 2007 (früher Gesetz über die elektromagnetische Verträglichkeit von Geräten), bzw. der EMV EG Richtlinie 2004/108/EC (früher 89/336/EWG), für Geräte der Klasse A.

Dieses Gerät ist berechtigt, in Übereinstimmung mit dem Deutschen EMVG das EG-Konformitätszeichen - CE - zu führen. Verantwortlich für die Konformitätserklärung nach Paragraph 5 des EMVG ist die Lenovo (Deutschland) GmbH, Gropiusplatz 10, D-70563 Stuttgart.

Informationen in Hinsicht EMVG Paragraph 4 Abs. (1) 4:

Das Gerät erfüllt die Schutzanforderungen nach EN 55024 und EN 55022 Klasse A.

Nach der EN 55022: "Dies ist eine Einrichtung der Klasse A. Diese Einrichtung kann im Wohnbereich Funkstörungen verursachen; in diesem Fall kann vom Betreiber verlangt werden, angemessene Maßnahmen durchzuführen und dafür aufzukommen."

Nach dem EMVG: Dieses Produkt entspricht den Schutzanforderungen der EU-Richtlinie 2004/108/EG (früher 89/336/EWG) zur Angleichung der Rechtsvorschriften über die elektromagnetische Verträglichkeit in den EU-Mitgliedsstaaten und hält die Grenzwerte der EN 55022 Klasse A ein.

Um dieses sicherzustellen, sind die Geräte wie in den Handbüchern beschrieben zu installieren und zu betreiben. Des Weiteren dürfen auch nur von der Lenovo empfohlene Kabel angeschlossen werden. Lenovo übernimmt keine Verantwortung für die Einhaltung der Schutzanforderungen, wenn das Produkt ohne Zustimmung der Lenovo verändert bzw. wenn Erweiterungskomponenten von Fremdherstellern ohne Empfehlung der Lenovo gesteckt/eingebaut werden.

Deutschland:

Einhaltung des Gesetzes über die elektromagnetische Verträglichkeit von Betriebsmitteln

Dieses Produkt entspricht dem "Gesetz über die elektromagnetische Verträglichkeit von Betriebsmitteln" EMVG (früher "Gesetz über die elektromagnetische Verträglichkeit von Geräten"). Dies ist die Umsetzung der EU-Richtlinie 2004/108/EG (früher 89/336/EWG) in der Bundesrepublik Deutschland.

Zulassungsbescheinigung laut dem Deutschen Gesetz über die elektromagnetische Verträglichkeit von Betriebsmitteln, EMVG vom 20. Juli 2007 (früher Gesetz über die elektromagnetische Verträglichkeit von Geräten), bzw. der EMV EG Richtlinie 2004/108/EC (früher 89/336/EWG), für Geräte der Klasse A.

Dieses Gerät ist berechtigt, in Übereinstimmung mit dem Deutschen EMVG das EG-Konformitätszeichen - CE - zu führen. Verantwortlich für die Konformitätserklärung nach Paragraph 5 des EMVG ist die Lenovo (Deutschland) GmbH, Gropiusplatz 10, D-70563 Stuttgart.

Informationen in Hinsicht EMVG Paragraph 4 Abs. (1) 4:

Das Gerät erfüllt die Schutzanforderungen nach EN 55024 und EN 55022 Klasse A.

Nach der EN 55022: "Dies ist eine Einrichtung der Klasse A. Diese Einrichtung kann im Wohnbereich Funkstörungen verursachen; in diesem Fall kann vom Betreiber verlangt werden, angemessene Maßnahmen durchzuführen und dafür aufzukommen."

Nach dem EMVG: "Geräte dürfen an Orten, für die sie nicht ausreichend entstört sind, nur mit besonderer Genehmigung des Bundesministers für Post und Telekommunikation oder des Bundesamtes für Post und Telekommunikation betrieben werden. Die Genehmigung wird erteilt, wenn keine elektromagnetischen Störungen zu erwarten sind." (Auszug aus dem EMVG, Paragraph 3, Abs. 4). Dieses Genehmigungsverfahren ist nach Paragraph 9 EMVG in Verbindung mit der entsprechenden Kostenverordnung (Amtsblatt 14/93) kostenpflichtig.

Anmerkung: Um die Einhaltung des EMVG sicherzustellen sind die Geräte, wie in den Handbüchern angegeben, zu installieren und zu betreiben.

Japan VCCI Class A Statement

この装置は、クラス A 情報技術装置です。この装置を家庭環境で使用すると電波妨害を引き起こすことがあります。この場合には使用者が適切な対策を講ずるよう要求されることがあります。 VCCI-A

This is a Class A product based on the standard of the Voluntary Control Council for Interference (VCCI). If this equipment is used in a domestic environment, radio interference may occur, in which case the user may be required to take corrective actions.
